

Confidence and the Propagation of Demand Shocks

George-Marios Angeletos¹ Chen Lian²

¹MIT and NBER

²UC Berkeley

November 13, 2020

Outline

- 1 Introduction
- 2 Element 1: Variable Utilization \Rightarrow AS Responds to AD
- 3 Element 2: Rational Confusion \Rightarrow Confidence Multiplier
- 4 Extensions and Discussion

Popular Narrative

- Household deleveraging or other AD shocks
 - ⇒ Consumers spend less
 - ⇒ Firms produce and hire less
 - ⇒ Consumers lose confidence and spend even less
 - ⇒ Firms produce and hire even less
 - ⇒ ...
 - ⇒ The Great Recession!

Does It Make Sense?

In RBC: **no**

- In GE, interest rates adjust, offsetting AD shock (Barro & King)

In NK: **perhaps**

- Only when MP does not replicate flexible price outcomes
- Effects of AD shock = monetary contraction
- Inflation and output co-move

BUT

- ZLB constraint not relevant in earlier recessions
- Inflation & output do not necessarily co-move in the data
 - ▶ Mavroeidis et al., (14)
- Non-inflationary demand shocks prevalent
 - ▶ Beaudry & Portier (13); Angeletos, Collard, Dellas (20)

This Paper

- A “minimum” theory of AD driven fluctuations with **flexible prices**

Element 1:

- **Variable utilization** + adjustment cost of capital
 - ▶ \Rightarrow intertemporal substitution in production
 - ▶ \Rightarrow **AS responds to AD**
- Literature: *static* utilization choices

Element 2:

- **Rational confusion** between idiosyncratic & agg. income fluctuations
- \Rightarrow **Confidence multiplier**
 - ▶ feedback loop between output, consumer & investor expectations
- A broader bounded rationality interpretation

Prediction:

- **u, y, h, c, i comove without TFP & π**

Outline

- 1 Introduction
- 2 Element 1: Variable Utilization \Rightarrow AS Responds to AD
- 3 Element 2: Rational Confusion \Rightarrow Confidence Multiplier
- 4 Extensions and Discussion

Preferences and AD Curve

- Preference (representative agent & complete info)

$$\mathcal{U}(c_t, n_t) + \beta_t \mathcal{U}(c_{t+1}, n_{t+1}) + \beta_t \beta_{t+1} \mathcal{U}(c_{t+2}, n_{t+2}) + \dots,$$

where

$$\mathcal{U}(c, n) = \frac{c^{1-\frac{1}{\sigma}}}{1-\frac{1}{\sigma}} - \frac{n^{1+\frac{1}{\nu}}}{1+\frac{1}{\nu}}$$

$$\log \beta_t = (1 - \rho_\beta) \log \beta + \rho_\beta \log \beta_{t-1} - \underbrace{\log \eta_t}_{\text{AD shock}}$$

- A positive η_t shock = urge to consume = positive AD shock
- AD curve (log-linearized, complete info)

$$y_t = -\sigma(R_t + \beta_t) + \mathbb{E}_t[y_{t+1}]$$

Technology and AS Curve

- Technology

$$y_t = (l_t)^\alpha (u_t k_t)^{1-\alpha}$$

$$k_{t+1} = (1 - \delta(u_t) + \Psi(l_t)) k_t,$$

- Tentatively: shut down $\Psi(l_t)$ (infinite adjustment cost)

Technology and AS Curve

- Technology

$$y_t = (l_t)^\alpha (u_t k_t)^{1-\alpha}$$
$$k_{t+1} = (1 - \delta(u_t) + \Psi(l_t)) k_t,$$

- Tentatively: shut down $\Psi(l_t)$ (infinite adjustment cost)
- AS curve (log-linearized):

$$y_t = (1 - \tilde{\alpha})(u_t + k_t),$$
$$u_t = \frac{\beta}{\tilde{\alpha} + \beta\phi} R_t + \beta \mathbb{E}_t[u_{t+1}],$$
$$k_{t+1} = k_t - \kappa u_t,$$

where $\tilde{\alpha} \equiv 1 - \frac{(1-\alpha)(1+\frac{1}{v})}{1+\frac{1}{v}-\alpha+\frac{\alpha}{\sigma}}$ and $\phi \equiv \frac{\delta''(u^*)u^*}{\delta'(u^*)}$.

Equilibrium without Info Frictions

- R not P : Intertemporal “Econ 101”
- RBC/flexible price core of NK: Vertical AS
- Here: natural rate of output responsive to AD

Outline

- 1 Introduction
- 2 Element 1: Variable Utilization \Rightarrow AS Responds to AD
- 3 Element 2: Rational Confusion \Rightarrow Confidence Multiplier
- 4 Extensions and Discussion

Full Model with Information Frictions

Supply side

- Complete info, same as above

Demand side

- Islands & idiosyncratic shocks
- Know own discount rate, own income & own interest rates
- **Incomplete info** about, or inattention to, aggregate conditions
- **Rational confusion** of idiosyncratic & agg. income fluctuations

AD Curve

Prop. The AD Curve

$$y_t = -\sigma \{R_t + \beta_t\} + \mathbb{E}_t[y_{t+1}] + (\mathcal{B}_t + \mathcal{G}_t).$$

- \mathcal{B}_t captures misperception of permanent income

$$\mathcal{B}_t \equiv \frac{1-\beta}{\beta} \sum_{k=0}^{+\infty} \beta^k \int \left(E_t^h [y_{h,t+k}] - \mathbb{E}_t [y_{h,t+k}] \right) dh,$$

where $y_{h,t} = y_t + \xi_{h,t}$ is the local income at t .

- \mathcal{G}_t captures misperception of future interest rates

$$\mathcal{G}_t \equiv -\sigma \sum_{k=1}^{+\infty} \beta^k \int \left(E_t^h [R_{t+k}] - \mathbb{E}_t [R_{t+k}] \right) dh$$

\mathcal{B}_t : Misperception of Permanent Income

Prop. Pro-cyclical perceived permanent income

$$\mathcal{B}_t = \frac{1-\beta}{\beta(1-\beta\rho_\xi)} (1-\lambda) \frac{\partial y_t}{\partial \eta_t} \eta_t$$

- ρ_ξ is the persistence of the idiosyncratic income shock $\xi_{h,t}$
- $1-\lambda$: degree of confusion between idiosyncratic & agg.

Mechanism: current aggregate income y_t drops

⇒ local income $y_{h,t} = y_t + \xi_{h,t}$ drops

⇒ rationally confused as drop in idiosyncratic income $\xi_{h,t}$

⇒ drop in perceived permanent income

\mathcal{B}_t : Misperception of Permanent Income

Prop. Pro-cyclical perceived permanent income

$$\mathcal{B}_t = \frac{1-\beta}{\beta(1-\beta\rho_\xi)} (1-\lambda) \frac{\partial y_t}{\partial \eta_t} \eta_t$$

- ρ_ξ is the persistence of the idiosyncratic income shock $\xi_{h,t}$
- $1-\lambda$: degree of confusion between idiosyncratic & agg.

Mechanism: current aggregate income y_t drops

⇒ local income $y_{h,t} = y_t + \xi_{h,t}$ drops

⇒ rationally confused as drop in idiosyncratic income $\xi_{h,t}$

⇒ drop in perceived permanent income

\mathcal{B}_t independent of the persistence of the AD shock ρ_β (Hulten)

- Aggregate permanent income invariant to the AD shock

$$\sum_{k=0}^{+\infty} \beta^k \int \mathbb{E}_t [y_{t+k}] = \frac{1-\tilde{\alpha}}{1-\beta} k_t$$

Confidence Multiplier

\mathcal{G}_t : Discounting GE Interest Rate Adjustment

Prop. Misperception of Future Interest Rate Adjustment

$$\begin{aligned}\mathcal{G}_t &\equiv -\sigma \sum_{k=1}^{+\infty} \beta^k \int \left(E_t^h [R_{t+k}] - \mathbb{E}_t [R_{t+k}] \right) dh \\ &= (1 - \lambda) \frac{\sigma^2}{\sigma + \zeta} \frac{\beta \rho_\beta}{1 - \beta \rho_\beta} \eta_t\end{aligned}$$

Persistent negative AD shock

- Neoclassical GE: future interest rate R_{t+k} drops
 - ▶ goes against the impact of the AD shock
- Here: cannot fully perceive R_{t+k} drop
 - ▶ Further **amplifies** the impact of the AD shock

Literature: **dampens** the impact of forward guidance

- Strategic substitutability (here) vs complementarity (NK)

Full Equilibrium

Prop. Two Multipliers

The equilibrium response of aggregate output is given by

$$\frac{\partial y_t}{\partial \eta_t} = \gamma \cdot m^{\text{conf}}(\lambda, \rho_\xi) \cdot m^{\text{GE}}(\lambda, \rho_\beta),$$

where $\gamma > 0$ is frictionless response and $m^{\text{conf}}(\lambda, \rho_\xi), m^{\text{GE}}(\lambda, \rho_\beta) > 1$.

- Both $m^{\text{conf}}(\lambda, \rho_\xi)$ and $m^{\text{GE}}(\lambda, \rho_\beta)$ increase with the confusion $1 - \lambda$
- $m^{\text{conf}}(\lambda, \rho_\xi)$ increases with the persistence of idiosyncratic shock ρ_ξ
- $m^{\text{GE}}(\lambda, \rho_\beta)$ increases with the persistence of AD shock ρ_β

Full Equilibrium

Prop. Two Multipliers

The equilibrium response of aggregate output is given by

$$\frac{\partial y_t}{\partial \eta_t} = \gamma \cdot m^{\text{conf}}(\lambda, \rho_\xi) \cdot m^{\text{GE}}(\lambda, \rho_\beta),$$

where $\gamma > 0$ is frictionless response and $m^{\text{conf}}(\lambda, \rho_\xi), m^{\text{GE}}(\lambda, \rho_\beta) > 1$.

- Both $m^{\text{conf}}(\lambda, \rho_\xi)$ and $m^{\text{GE}}(\lambda, \rho_\beta)$ increase with the confusion $1 - \lambda$
- $m^{\text{conf}}(\lambda, \rho_\xi)$ increases with the persistence of idiosyncratic shock ρ_ξ
- $m^{\text{GE}}(\lambda, \rho_\beta)$ increases with the persistence of AD shock ρ_β

Bounded rationality interpretations:

- $m^{\text{conf}}(\lambda, \rho_\xi)$: Extrapolation/one-state representation
- $m^{\text{GE}}(\lambda, \rho_\beta)$: Level-k thinking

Outline

- 1 Introduction
- 2 Element 1: Variable Utilization \Rightarrow AS Responds to AD
- 3 Element 2: Rational Confusion \Rightarrow Confidence Multiplier
- 4 Extensions and Discussion

Comovement: Borrowers and Savers

Standard: borrowers “credit crunch”

$$c_t^b = -\sigma R_t + \mathbb{E}_t [c_{t+1}^b] - \sigma \beta_t$$

$$c_t^s = -\sigma R_t + \mathbb{E}_t [c_{t+1}^s],$$

- Borrower & saver **negatively co-move** (R_t adjusts)

Here:

$$c_t^b = -\sigma R_t + \mathbb{E}_t [c_{t+1}^b] + \mathcal{B}_t + \mathcal{Y}_t - \sigma \beta_t$$

$$c_t^s = -\sigma R_t + \mathbb{E}_t [c_{t+1}^s] + \mathcal{B}_t + \mathcal{Y}_t$$

Prop. Borrowers and Savers

With strong enough info friction, (c_t^s, c_t^b, y_t) **positively co-move**.

Difference from NK: no need for ZLB/constrained monetary policy

Comovement: Investment

$$k_{t+1} = [1 - \delta(u_t) + \Psi(l_t)] k_t.$$

Complete info (with small wealth effect on labor supply)

- **Negative comovement between i and c**
 - ▶ negative AD shock, $c \downarrow$, $R \downarrow$, $i \uparrow$

Our resolution:

- **Investment** subject to **confidence multiplier** too
- Feedback between y_t & investor expectations of returns
- With large enough friction, $(c_t, l_t, y_t, n_t, u_t)$ **positively co-move**.

Government Spending

Q: How does confidence multiplier impact fiscal policy?

Here, for simplicity, shut down wealth effect of G on labor supply

- Same AS as above

AD:

$$y_t = -\sigma R_t + G_t - E_t[G_{t+1}] + E_t[y_{t+1}] + (\mathcal{B}_t + \mathcal{G}_t)$$

Front-loading $G_t \implies$ positive AD shock \implies confidence multiplier

Prop. Front-loading government spending

With strong enough info friction, G_t can **crowd in** c_t

Back-loading $G_t \implies$ negative AD shock \implies negative multiplier

AD Shocks vs AS Shocks

- Replace the AD shock with **an aggregate TFP shock**
- Maintain same info assumptions
- **No confidence multiplier**
 - ▶ Actual permanent income moves with aggregate TFP
 - ▶ Rational confusion \implies Ambiguous \mathcal{B}_t
 - ▶ Useful benchmark $\mathcal{B}_t \approx 0$ ($\rho_\xi \approx \rho_A$)
- GE discounting has **reverse effect**
 - ▶ Negative TFP Shock \implies positive $R_t \implies$ **Positive** \mathcal{G}_t

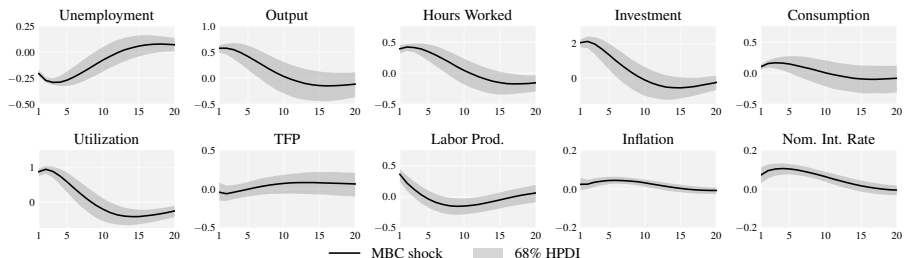

Prop. TFP Shock

Info friction dampens the **relative** impact of AS vs AD shock

- Consistent with the importance of non-inflationary AD shock

Circling Back to Motivating Facts

- Main Business Cycle Shock (Angeletos, Collard, Dellas, 20)

- u, y, h, c, i comove without TFP & π
- Evidence of intertemporal substitution in production
- Utilization accounts for pro-cyclicality in labor prod
- Non-accommodative MP and procyclical real R

Conclusion

Contributions:

- A theory of demand-driven fluctuations without sticky prices
- A theory of amplifications for AD shock (but not AS shocks)
- A theory of comovement among business cycle variables
 - ▶ but not with *TFP* or inflation

Not to replace NK, but to **strengthen its “flexible-price” core**

- Main insights go through sticky prices
