Conference draft: May 18, 2020

*** Preliminary and Comments Welcome ***

Abstract

This paper considers the treatment of co-benefits in benefit-cost analysis of federal air quality regulations. Using a comprehensive dataset on all economically significant Clean Air Act rules issued by the EPA over the period 1997-2016, we show that (1) co-benefits make up a significant share of the monetized benefits; (2) among the categories of co-benefits, those associated with reductions in fine PM are the most significant; and (3) co-benefits have been pivotal to the quantified net benefit calculation in the majority of cases. Motivated by these trends, we develop a simple conceptual framework that illustrates a critical point: co-benefits are simply a semantic category of benefits that should be included in benefit-cost analyses. We also address common concerns about whether the inclusion of co-benefits is problematic because of alternative regulatory approaches that may be more cost effective and the possibility for double counting.

* This paper was prepared for inclusion in the *Environmental and Energy Policy and the Economy* conference and publication, sponsored by the National Bureau of Economic Research (NBER). We are grateful to Sofia Caycedo and Tim Bialecki while students at Yale for valuable research assistance.

1. Introduction

Social benefit-cost analysis (BCA) is a useful and widely employed tool for informing and evaluating public policy decision-making. Its primary objective is to assess whether a particular policy or policy proposal promotes economic efficiency compared to a baseline scenario. At the most general and comprehensive level, BCA is a systematic aggregator of all anticipated or realized impacts, positive and negative, to all relevant parties, and at all relevant points in time. The benefit-cost criterion is simply a test of whether the benefits exceed the costs: if the net benefits are positive, then the policy promotes economic efficiency compared to the baseline status quo.

The use of BCA among agencies of the U.S. federal government has a long bipartisan history. President Reagan established a requirement for regulatory actions such that “the potential benefits to society for the regulation outweigh the potential costs to society” (EO 12291). As part of this objective, the Reagan administration also required agencies to produce a regulatory impact analysis (RIA)—in effect, a BCA in most cases—of major rules.¹ President Clinton continued the requirement for BCA, though modified the standard so that agencies “shall assess both the costs and the benefits of the intended regulation and, recognizing that some costs and benefits are difficult to quantify, propose or adopt a regulation only upon a reasoned determination that the benefits of the intended regulation justify its costs” (EO 12866). Every administration since has employed this same approach to guide its review of federal regulations, including most recently the Trump administration, which added new provisions seeking to manage overall regulatory costs (EO 13771, OMB 2017).

BCA has played a particularly important role in support of federal regulations aimed at protecting human health and environmental quality. Those analyses applied to regulations focused on improving air quality often yield the greatest quantified costs and benefits of all regulations across government agencies. For example, in a review of all new federal regulations during the 10-year period from FY 2007 to FY 2016, OMB (2019) finds that Environmental Protection Agency (EPA) rules account for between 80%-84% of all monetized benefits and 63%-71% of all monetized costs.² Moreover, rules coming out of the EPA’s Office of Air and Radiation in particular are found to have especially high net benefits.

The anticipated impacts of many federal policies are broad, with some benefits and costs directly linked to the policy’s intended focus and other benefits and costs arising only indirectly. Nevertheless, BCAs conducted in line with best practices seek to count all significant benefits and costs, whether or not they arise as a direct result of the policy’s intended objectives or as a result of an ancillary change attributed to the policy. Historically, BCAs conducted by the EPA have treated ancillary benefits and costs in ways consistent with economic theory and regulatory guidance—on an equal footing with benefits more directly linked to the policy. Recently, however, the EPA has made decisions and solicited feedback that

¹ A major rule is one that has an impact of \$100 million or more in at least one year. Only a small fraction of final rules are considered major. According to OMB (2019), for example, only 609 out of 36,255 final rules published in the *Federal Register* from FY 2007 to FY 2016, or 1.7%, meet the major designation.

² Calculation includes 4 rules jointly promulgated by EPA and the Department of Transportation (DOT). See Table 1-1 on pp. 7-8.

indicate a potential shift in—or at least questioning of—its treatment of ancillary benefits and costs, referred to here as generally as “co-benefits” and “co-costs.”³

It is within this context that the present paper considers the treatment of co-benefits in BCAs, with a particular focus on air quality regulations, where the issues have become front and center. Specifically, the paper has two primary objectives:

1. Provide a descriptive overview of the role co-benefits have played in the BCAs of federal air quality regulations using detailed data from all available RIAs, 1997 to the present.
2. Develop a simple theoretical framework to clarify how co-benefits are simply another category of benefits that should be included in BCAs, yet identify some of the unique challenges that arise for measuring them well.

The next section provides background on co-benefits in the context of energy and environmental policy and recent policy actions. Section 3 describes our data collection, reports a range of descriptive statistics and trends over time, and discusses a few specific cases to illustrate some key issues that arise. Section 4 develops a theoretical framework that introduces some key concepts and definitions, and explicitly addresses some of the concerns raised about co-benefits. Section 5 concludes with a summary of our key findings and observations about the political economy of why co-benefits have become increasingly important and a growing topic of concern.

2. Background and Recent Actions

A. Co-Benefits and Co-Costs

Co-benefits (or co-costs) arise when compliance with a regulation leads to benefits (or costs) that are not directly tied to a regulation’s intended target. While we focus on air quality regulations, the notions of co-benefits and co-costs are not unique to this setting. Consider, for example, the Emergency Highway Energy Conservation Act of 1974, which established a speed limit of 55 miles per hour. The purpose was to “conserve fuel during periods of current and imminent fuel shortages” and thus the direct benefits of the Act included fuel savings. However, a co-benefit of the Act was reduced road fatalities (Friedman et al., 2009). Another example is the Americans with Disabilities Act, which mandated curb cuts to benefit individuals in wheelchairs, but the change also benefited other pedestrians (e.g., pushing strollers or heavy carts, wheeling luggage), and the latter category is considered a co-benefit (Blackwell, 2017).

There are many examples in the environmental economics literature where co-benefits and co-costs have played a role. Sigman (1996) shows that regulations of hazardous waste disposal lead to increases in air pollution emissions. Kotchen et al. (2006) conduct an ex post BCA of a hydroelectric project’s effect on river flows, yet the analysis accounts for the co-benefits of reduced emissions because of

³ We use the term co-benefits throughout the paper, though other terms are frequently used as well in the literature and government analyses in reference to the same concept. These include impacts characterized as “secondary,” “indirect,” and “ancillary,” among others. When referring to co-benefits, we also assume implicitly the possibility for negative benefits, i.e., co-costs.

displaced electricity generation from fossil fuels. In another example, Hansman, et al (2018) show that a regulation designed to limit overfishing exacerbates air pollution from fishmeal processing plants.

A growing literature also explores the local air pollution implications of policies targeting greenhouse gas (GHG) emissions and climate change. Lutter and Shogren (2002) illustrate how regulating carbon dioxide (CO₂) emissions under a cap-and-trade program affects local air quality benefits, primarily through reductions of particulate matter (PM). Burtraw et al. (2003) show co-benefits of taxing CO₂ emissions in the form of reduced nitrous oxide (NO_x) emissions and lower compliance costs with other NO_x and sulfur dioxide (SO₂) regulations. More generally and recently, Karlson et al. (2020) review 239 peer-reviewed studies that assess the co-benefits of climate mitigation policies, and they find that most studies focus on air pollution related benefits, where the co-benefits themselves often outweigh compliance costs. Other co-benefits that emerge from their review include enhancements to biodiversity, energy security, and water quality.

Overall, the range of studies in the academic literature recognize that the ancillary pollutant effects could either worsen or improve as a consequence of regulating the targeted pollutant. Moreover, these examples illustrate the appropriateness and importance of accounting for both co-benefits and co-costs.

B. Regulatory Guidelines

Federal agencies have formally recognized the potential importance that co-benefits and co-costs can have in their rulemakings. They have therefore developed guidance for systematically accounting for these indirect effects in evaluations of regulatory proposals. The OMB, which is responsible for reviewing major regulations before they are finalized, directs all agencies to account for co-benefits and co-costs in its guidance for agency RIAs. It states that when evaluating the benefits and costs of regulations, agencies should “Identify the expected undesirable side-effects and ancillary benefits of the proposed regulatory action and the alternatives. These should be added to the direct benefits and costs as appropriate” (OMB 2003, pp. 2-3). This general guidance makes clear that the scope of regulatory analysis extends beyond determining whether the regulation achieves the statute’s primary goal. That is, co-benefits and co-costs should be included in the analysis.

The EPA’s existing *Guidelines for Preparing Economic Analyses*, with specific provisions for conducting BCAs, likewise calls for explicit accounting of co-benefits and co-costs. It states that, “An economic analysis of regulatory or policy options should present all identifiable costs and benefits that are incremental to the regulation or policy under consideration. These should include directly intended effects and associated costs, as well as ancillary (or co-) benefits and costs” (EPA 2014, p. 11-2).

C. Co-Benefits and the Clean Air Act

Air quality regulations have a long history of delivering multiple types of social benefits, including co-benefits. Some of these were accounted for in the design stages of the Clean Air Act (CAA), others were not fully understood until after CAA regulations were introduced. Here we review several examples.

To reduce air pollution from cars and light trucks, EPA has often regulated both vehicles and the fuels they use. This system-based approach has delivered multiple emissions benefits. In 1973, EPA promulgated a regulation requiring gasoline stations to market unleaded gasoline. This regulation was

motivated by the fact that lead in the fuel harmed catalytic converters, a new technology mandated by other CAA regulations intended to reduce tailpipe emissions of carbon monoxide. EPA subsequently established a national ambient air quality standard for lead in 1976. Removing lead from gasoline therefore delivered on two air quality objectives in the 1970s and 1980s: reducing ambient concentrations of carbon monoxide and of lead.

The 1990 CAA Amendments authorized the first cap-and-trade program for power plant SO₂ emissions. The risks posed by acid rain—including the acidification of forests and waterbodies—were the primary motivation (Schmalensee and Stavins 2013). Most of the monetized benefits, however, have resulted from reducing human exposure to fine PM that contributes to premature mortality. In this case, the sizeable health benefits caused by the reduction in SO₂—an important precursor to PM formation—were not fully appreciated or anticipated at the time the regulation was implemented. Ex post advances in epidemiology in the 1990s began to identify and estimate the public health risk of fine PM.

Another prominent example is from 2015, when the EPA promulgated the Clean Power Plan to reduce CO₂ emissions in the power sector. Co-benefits played an important role in this rulemaking because it was anticipated that, in the process of reducing CO₂, power plants would also significantly reduce SO₂ and NO_x, with subsequent reductions in fine PM and ozone because of chemical precursor relationships. As a result, the agency projected billions of dollars of monetized benefits per year from mitigating climate change and billions of dollars of monetized benefits per year from reducing premature mortality due to reduced exposure to ambient PM and ozone. As shown in Section 3, accounting for co-benefits has been the norm for economically significant CAA regulations issued by the EPA over the past several decades.

Sometimes Congress has specifically amended legislation to expand the target objectives of existing rules, effectively converting co-benefits into targeted benefits. This has happened notably in the case of rules targeted at fossil fuel consumption being expanded to mitigate climate change. For example, the 1975 Energy Policy and Conservation Act created the corporate average fuel economy standards and introduced fuel economy labels for new vehicles in response to the 1973-74 oil shock. The goal was to reduce fuel consumption. The 2007 Energy Independence and Security Act added the goal of reducing GHG emissions, setting more ambitious fuel efficiency standards and directing the DOT to revise fuel economy labels to include information about GHG emissions.

The 2005 Energy Policy Act amended the CAA to create the renewable fuel standard with annual goals for biofuel consumption intended to displace petroleum-based transportation fuels. The 2007 Energy Independence and Security Act revised this program by setting more ambitious biofuel volume goals and mandating multiple low-carbon biofuel categories so that the policy could simultaneously reduce oil consumption and CO₂ emissions.

D. Recent Actions Related to the Inclusion of Co-Benefits and Co-Costs

Despite the important role that co-benefits (and co-costs) have played in shaping outcomes under past CAA regulations, and the well-established regulatory guidance about including them, the EPA has undertaken recent actions with the potential to diminish the value of co-benefits and/or question their inclusion in economic analyses.

EPA Science Transparency Proposed Rule, 2018.— EPA issued the proposed rule in the name of improving transparency and replicability of the science underlying its assessment of regulatory benefits and costs. The initial proposal focused on limiting the Agency’s use of dose-response functions to those developed using publicly available data and models that could be used for independent replication. In a supplement released in March 2020, EPA 1) proposed extending the requirement beyond dose-response functions, 2) sought comment on tiered access to study data, and 3) proposed decision-making rules that place lower weight on studies based on confidential data. While not explicitly concerned with co-benefits, these proposals will weaken or eliminate consideration of most of the epidemiological studies on the health effects of fine PM that underlie the calculation of many co-benefit estimates. They could also eliminate consideration of virtually all studies used to determine the value of a statistical life (e.g., labor market hedonic studies based confidential data, and stated preference studies), for in many cases, these studies are done with the understanding that individual information will be kept confidential and thus not made publicly available.

EPA Consistency and Transparency in Benefit-Cost Analysis Proposed Rule, 2018.— EPA solicited public feedback on the conduct of BCAs, including the following: “What improvements would result from a general rule that specifies how the Agency will factor the outcomes or key elements of the benefit-cost analysis into future decision making? For example, *to what extent should EPA develop a general rule on how the Agency will weigh the benefits from reductions in pollutants that were not directly regulated (often called “co-benefits” or “ancillary benefits”)...?* (EPA 2018b, p. 27527; emphasis added)” In 2019, Administrator Wheeler then directed agency staff to develop reforms on the practice of BCA on a media-specific basis. The Administrator also requested the ongoing update of EPA’s *Guidelines for Preparing Economic Analyses*.

EPA Affordable Clean Energy Final Rule, 2019.— EPA issued a replacement for the 2015 Clean Power Plan, which set CO₂ emissions standards for existing power plants, known as the Affordable Clean Energy rule or ACE. In its presentation of the benefits and costs of ACE, EPA presented tables reflecting all benefits and costs, along with a separate table that includes only the information for the targeted pollutant. This additional table indicated that without the co-benefits the ACE rule does not yield positive net benefits, due in large part because the targeted pollutant benefit calculation reflects only domestic climate benefits. The presentation of results in this way is significant because it signals a shift within the EPA that all benefits are not counted on an equal footing.

EPA/DOT Tailpipe CO₂/Fuel Economy Final Rule, 2020.— The EPA’s new approach to the ancillary impacts of regulation does not, however, appear to be consistently applied across rulemakings. For example, the revision to the EPA tailpipe CO₂ emission standards and NHTSA fuel economy rules issued in 2020 included (i) potential changes in traffic fatalities arising because of automaker compliance strategies, and (ii) increased congestion as a rationale for reducing the stringency of the regulations. These ancillary changes were included in the calculations of the total net benefits of the rule, not weighted differently from the primary objectives of EPA’s authority for the regulations under Title II of the CAA.

EPA Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources Review, 2019.— The proposed amendments to the New Source Performance Standards (NSPS) for the oil and gas sector further illustrate EPA’s inconsistent regulatory treatment of co-benefits. In the case of

this proposed rule, EPA uses the co-benefit relationship between methane and volatile organic compounds (VOCs) to support its proposal to rescind the methane-specific requirements of the NSPS.⁴ Specifically, EPA (2019b) argues that the methane-specific requirements “are entirely redundant of the existing NSPS for VOCs” (p. 50254).

EPA MATS Appropriate and Necessary Determination, 2020.— EPA finalized a new rule reversing its previous finding on the legal basis of the Mercury and Air Toxics Standards (MATS), a regulation designed to reduce the emissions of mercury and other hazardous air pollutants (HAPs) from power plants. Whereas the EPA concluded in 2011 and 2016 that it was “appropriate and necessary” to regulate mercury and other HAPs under authority of the CAA, it concludes the opposite in 2020. The rationale rests largely on dismissing the co-benefits of reducing fine PM, which accounted for the vast majority of quantified benefits in the original 2011 RIA (Aldy et al. 2019, 2020). The EPA’s rationale is that only the target pollutant benefits should count when making the legal determination, thereby narrowing the scope of what benefits should count.

Draft Guidelines for Preparing Economic Analyses, 2020.— In April 2020, the EPA released a draft of its updated *Guidelines for Preparing Economic Analyses*. While it does not raise questions about whether or not co-benefits should be included in BCAs, the draft does make recommendations about what the Agency should do in cases where co-benefits are large: “When the benefits associated with reductions in these other contaminants [co-benefits] are a large share of total benefits, or net-benefits would be negative without them, the analysis should describe other options that directly regulate those contaminants. Furthermore, an analysis of a policy option in which the other contaminant(s) are regulated directly, either separately or simultaneously with the regulation being analyzed, may be warranted. Correspondingly, there may be costs from increases in environmental contaminants other than those related to the statutory objective of the regulation that occur as a result of the regulatory action. As noted, analysis of additional options to mitigate these effects may be warranted if they are large” (EPA 2020, p. 3-6). We discuss these recommendations later in the paper in the context of our conceptual framework.

3. Trends and Patterns Across Clean Air Act RIAs

We now examine more long-term trends and patterns in the role of co-benefits in EPA analysis of CAA rules and regulations. We begin with an overview of our data collection and preparation, before turning to the results of our analysis.

A. Constructing the Sample

We focus on the category of economically significant rules, since these consistently have well-developed assessments of the economic impacts of the regulations in question. We reviewed the OMB annual reports to Congress on the benefits and costs of regulations to identify all economically significant CAA rules issued by EPA over the period 1997-2016. We provide further details in the Appendix along with

⁴ EPA (2019b) seeks comments on two proposals to rescind methane-specific requirements. The first proposal would remove the requirements only for the production and processing segments. The alternative proposal would rescind the methane-specific requirements for oil and natural gas sources.

full citations and hyperlinks to all rules and RIAs compiled in our dataset. Over this 20-year period, EPA issued 49 economically significant regulations, and Figure 1 shows the number of rules issued in each year. In some cases, especially for rules promulgated in the 1990s, EPA conducted cost-effectiveness analysis rather than a BCA. This means that those RIAs focus on estimating the regulatory expenditures per ton of emissions reduced, rather than on estimating the monetized value of air quality benefits. After excluding these cases, we compiled a sample of 40 air quality rules for which EPA published a prospective BCA that explicitly monetizes at least some of the rule’s benefits in its RIA.⁵

Figure 1: Number of Economically Significant CAA Regulations Promulgated by EPA, 1997-2016. Annual counts produced by the authors based on a review of OMB reports to Congress.

B. Distinguishing Between “Targeted Benefits” and “Co-benefits”

To determine the “targeted” benefits of a rule and distinguish these from the “co-benefits” required review of both the RIA and the promulgated regulation. An EPA rule describes the relevant statutory authority or authorities that motivate the regulatory action, which can often identify the pollutant or pollutants “targeted” under the law. The rule and the RIA also describe the specific emission standards by pollutant, and the identification of each pollutant that must be monitored under the rule is one way to identify those that are “targeted.” There are, however, a variety of cases in which the “targeted” benefit is identified in the statutory authority, yet the specific emission standards set in the rule apply to

⁵ While the RIAs for some rules mention non-monetized benefits, given the nature of our analysis, we necessarily restrict attention to monetized benefits and costs.

emission precursors for that pollutant. An example is ozone as a targeted pollutant, with emissions standards that apply to the precursors of NO_x and VOCs.

In some cases, the identification of the “targeted” benefits appears quite straightforward. For example, EPA issued National Ambient Air Quality Standards (NAAQS) for lead, ozone, PM-2.5, and SO₂ during our sample period. These regulations set the maximum permissible ambient air quality concentrations for these specific air pollutants—and thus the “targeted” benefits of the lead standard, for example, are clearly associated with the reduction in lead pollution.

In other cases, the identification of the “targeted” benefits is more complicated. To illustrate some of the challenges involved and to describe our procedure, we walk through a particular example: the 1998 “NO_x SIP Call” rule (RIN 2060-AH10)⁶. The rule was clearly motivated by the need to address the cross-state transport of ozone pollution and the adverse public health consequences of high ambient ozone concentrations (Napolitano et al. 2007). Indeed, it built on and expanded from the then-existing Ozone Transport Commission NO_x trading program for Mid-Atlantic and Northeast states (Linn 2008). In order to achieve reductions in ozone, the rule focused on NO_x, a precursor to atmospheric ozone. The monetized benefits of the rule arise from reductions of ozone, fine PM, and water pollution through nitrogen deposition

A key question in this case, therefore, is whether to treat the “targeted” pollutant as ozone or NO_x, as this has important consequences for the categorization of benefits. We treat ozone as the targeted pollutant because of the rule’s clear intent and classify the benefits associated with fine PM and water pollution as co-benefits.

More generally, we apply the following classification procedures for identifying the monetized “targeted” benefits from the monetized “co-benefits.” First, we review the rule as published in the Federal Register to identify specific statutory authorizations. Second, we review the rule and the RIA for information on specific pollutant emission standards. Third, we review the rule and the RIA to assess how regulating a precursor pollutant may connect to the targeted pollutant under the statutory authority. Finally, we account for (but do not automatically follow) EPA’s specific description of some benefits as co-benefits.

Two further conventions that we employ are worth mentioning to clarify how we made classifications. The first is that all benefits directly associated with a “targeted” pollutant are considered “targeted” benefits. For example, ozone benefits of the NO_x SIP Call rule include those associated with ozone effects on worker productivity, commodity crop production, and commercial forest production; and all of these go beyond the public health focus of the primary NAAQS. The second convention is that when targeted pollutants are themselves precursors to other pollutants for which reductions lead to monetized benefits, these “downstream” benefits are considered co-benefits. This scenario is most common when the target pollutant is SO₂, which is a precursor for fine PM and often generates significant co-benefits.

⁶ We use Regulation Identifier Numbers (RINs) to identify each regulation we describe in the text. The appendix table lists all regulations with their RINs, publication dates, and Federal Register cites that we have compiled for this analysis.

Finally, we recognize that, for some rules, the classification procedures we employ require a degree of subjectivity. We have nevertheless sought to define categories in ways that respond to emerging concerns about the role of co-benefits within EPA RIAs. While a central part of our theoretical contribution later in the paper is that such categorizations should not matter in BCAs, having some empirical foundation upon which to anchor the discussion is important. We provide additional information in our data appendix, including a link to our database that can permit other scholars, analysts, and stakeholders to replicate, modify, and expand on this analysis.

C. Selecting Benefits and Costs Estimates

Few of the RIAs in our sample produce present values for the streams of costs and benefits over time. Notable exceptions are the joint EPA/National Highway Traffic Safety Administration (NHTSA) rules that address CO₂ emissions and fuel efficiency in vehicles. These RIAs produce annual streams of benefits and costs out to 2050.

The most common practice is to generate a “snapshot” estimate for the annual costs and benefits in a future year during “full implementation” of the rule. In many, but not all of these cases, the benefits are not discounted to produce a present value in the year the regulation is promulgated. They are the value of benefits and costs in some future year expressed in some base year dollar equivalent. In a subset of these cases, the premature mortality benefits associated with PM—some of which occur with a period of latency—are discounted back to the “snapshot” year at either a 3% or 7% discount rate. In addition, the benefits of reducing CO₂ emissions and methane (CH₄) emissions (using the social cost of carbon, SCC, and social cost of methane, SCCCH₄), which are spread out over hundreds of years, are based on a 2.5%, 3%, or 5% discount rate.

In some RIAs, the costs represent the amortization of capital and operating costs for complying with the regulation over a specified time horizon. This approach is typically estimated with a 7% discount rate. In other RIAs, the snapshot year costs are simply the estimated compliance costs for that year, and it is unclear the extent to which these snapshots account for initial investments in pollution control equipment. In a few rules, the underlying model for estimating compliance uses discount rates other than 3% or 7%. For example, the model runs used for the NO_x SIP Call rule are based on a 6% rate.

Many RIAs also present ranges of estimates. Some may reflect differences in assumptions on the premature mortality dose-response functions for ozone and particulate matter. Some may reflect a range over multiple implementation and compliance scenarios, especially in those cases where states have some discretion on how they implement the rule (e.g., the Regional Haze Regulations).

The preceding discussion means that it is challenging to construct a consistent set of benefits and costs that enables true apples-to-apples comparisons across RIAs. In our analysis, we have nevertheless endeavored to create a dataset that produces measures of benefits and costs that are as comparable as possible given information published in the RIAs. In general, we have opted for a full-implementation, snapshot year measure of benefits and costs based on a 7% discount rate, where discounting is applied to the extent possible.⁷ The SCC and some compliance costs calculations will be exceptions because of

⁷ We note that the choice of discount rate is less of a concern for this analysis because of the way that benefits and costs are reported for a given snapshot year. There are two categories of exceptions. First, some RIAs present

the differing rates used in the underlying analysis. While our database includes upper and lower bound estimates, we report results based on the average of the two unless otherwise indicated. All values are reported in 2019 dollars with conversions made using the standard GDP deflator.

Figure 2: Net Social Benefits of Clean Air Act RIAs, 1997-2016, based on one-year full-implementation snapshots of monetized benefits and costs. In each panel, regulations are ordered chronologically. The left panel presents results for all 40 regulations in our database. The right panel excludes regulations with net social benefits in excess of \$50 billion to better illustrate impacts of rules with smaller net economic impacts.

D. Results of Analysis of EPA Clean Air Act RIAs

The EPA regulatory program consistently delivers the greatest monetized benefits and imposes the largest costs of any federal regulatory agency’s actions. To provide context for an assessment of co-benefits, Figure 2 illustrates the net social benefits for the CAA regulations in our database. Every rule with two exceptions has positive net social benefits – based on the average of the lower and upper bounds of benefits and costs for that regulation’s snapshot of a full implementation year. One exception is the RIA for the 2008 NAAQS for lead (RIN 2060-AN83), which estimated about -\$90 million net social

latent fine PM premature mortality risks. These RIAs estimate the present value of these risks over five years from the snapshot year. Second, joint EPA/NHTSA regulations addressing fuel economy provide the present value of the benefits from vehicles regulated in the snapshot year.

benefits for the year 2016.⁸ The other is the RIA for the 2005 mercury power plant rule, Standards of Performance for New and Existing Stationary Sources: Electric Utility Steam Generating Units (RIN 2060-AJ65), which estimated about -\$1 billion in net social benefits for the year 2020. The median rule has about \$4 billion in net social benefits.

We find that co-benefits account for about 45 percent of the monetized benefits on average across all RIAs. As Figure 3 illustrates, this average masks considerable heterogeneity among the rules. Some rules have no monetized co-benefits, such as the 2013 fine PM NAAQS, which naturally targeted fine PM, and the 2014 Tier 3 motor vehicle and emission standards, which targeted fine PM and ozone. Other rules, especially several of those focused on HAPs, have zero monetized benefits for the targeted pollutant. In these cases, fine PM pollution reductions are the primary, if not exclusive, source for monetized benefits. There are three joint EPA/NHTSA regulations targeting carbon dioxide emissions and fuel economy. In these cases, we consider fuel economy one of the targets of the regulation, given NHTSA's statutory authority. If, however, we were to consider fuel economy a co-benefit from the standpoint of EPA under its Clean Air Act authority, then about \$130 billion of benefits over 2011-2016 would shift and several of the dark gray bars on the bottom of Figure 3 would fall substantially (RIN 2060-AP61, 2060-AQ54, and 2060-AS16).

The monetized co-benefits in CAA RIAs are primarily a story about fine PM. This has long been acknowledged by EPA and OMB, the latter in its annual reports to Congress on the benefits and costs of regulation. In our assessment, the fine PM identified as co-benefits represent 94% of all monetized co-benefits over 1997-2016. The other categories are visibility (3%), SO₂ (1%), ozone (<1%), CO₂ (<1%), and energy and electricity savings (<1%).

We should also note that there are several cases in which EPA estimated negative co-benefits because the regulation would increase emissions of a monetized pollutant. For example, the lower bound of the SO₂ co-benefits in the 1998 pulp and paper "cluster rule" are negative and the 2010 HAPs standards for Portland cement plants includes negative CO₂ co-benefits as a result of increased electricity demand expected under facilities' compliance strategies.

Co-benefits often play a pivotal role in determining the sign of net social benefits among the monetized categories of costs and benefits for many CAA regulations. About 47% of the regulations in our database have monetized benefits of the targeted pollutant exceeding the monetized costs (Figure 4). That is, these rules would show positive net benefits even without the inclusion of co-benefits. The flip side is that slightly more than half of the rules in our database would have negative net social benefits if co-benefits were omitted from the analysis. In the conclusion, we address the value of information and the political economy of when the agency may "stop counting" monetized benefits under the Clean Air Act.

⁸ In the lead NAAQS RIA, the lower bound benefits exceed the lower bound costs estimated with a 7% discount rate. Under a 3% discount rate, the lower and upper bounds of the monetized benefits exceed their corresponding scenario's costs.

Figure 3: The relative contribution of target pollutant benefits and co-benefits to total monetized benefits. Regulations are listed by Regulatory Identifier Number (RIN) and ordered chronologically from top to bottom spanning 1997-2016. The appendix lists each regulation with its associated RIN.

Some categories of rules have targeted benefits that consistently outweigh monetized costs. For example, 14 of the 15 rules that explicitly target fine PM have positive net social benefits based on an exclusive accounting of monetized benefits associated directly with the targeted pollutant. The joint EPA/NHTSA rules addressing tailpipe CO₂ emissions and fuel economy always have positive net social benefits based only on targeted benefits, and this follows because of our accounting of fuel economy as a primary motivation of these rules and the sizable fuel savings benefits estimated by the agencies.

Figure 4: Share of rules with target pollutant monetized benefits in excess of the monetized Costs, 1997-2016.

In contrast, regulations targeting HAPs – such as the National Emission Standards for Hazardous Air Pollutants – often have modest monetized benefits for the targeted pollutant. As Figure 5 illustrates, most regulations focused on HAPs have monetized target benefits less than the monetized costs. One reason for this, at least in the case of the MATS Rule, is that the science for and means of economic evaluation for mercury emissions have only evolved more recently, whereas the techniques for valuing the health consequences for fine PM are well-established. The value of monetizing additional benefits based on recent science within the context of RIAs of new air regulations is a topic to which we return later in the paper.

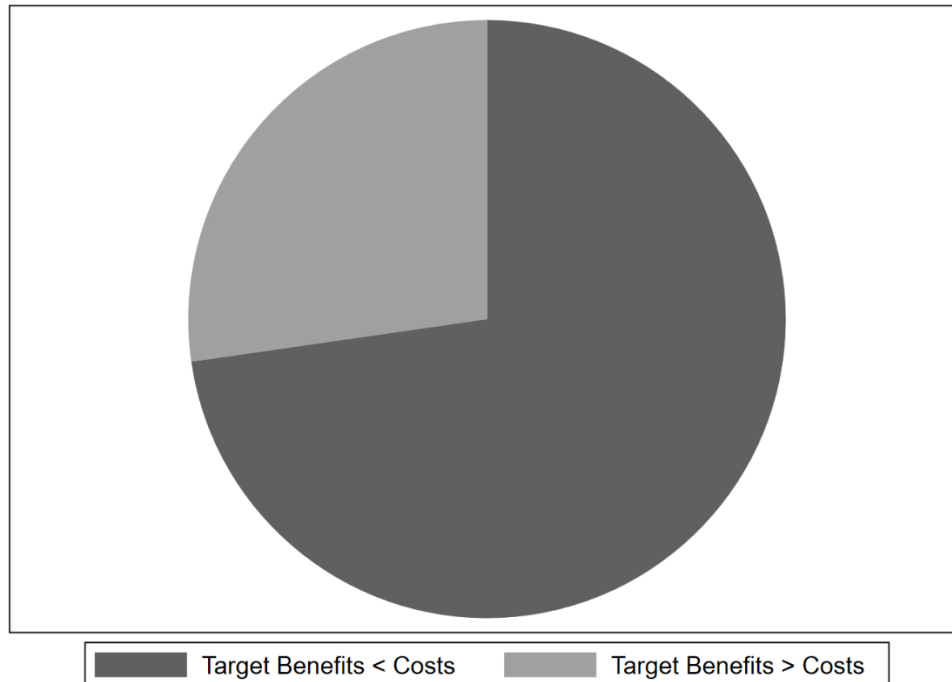

Figure 5: Share of rules targeting hazardous air pollutants (HAPs) with target pollutant monetized benefits in excess of the monetized costs

4. A Simple Theory of Co-benefits

The previous section demonstrates how EPA has been considering co-benefits in RIAs for decades. Have they been counted appropriately? While we do not answer this question on a case-by-case basis, this section describes a simple theoretical framework to help make such determinations. That is, we make the straightforward case for when co-benefits should or should not be fully counted in any BCA. We also address a few of the specific questions that have been raised about including co-benefits: (a) If co-benefits are large, wouldn't regulating them directly be more efficient or cost-effective? (b) How do we count co-benefits if the co-pollutant is already regulated? And (c) under what circumstances does the inclusion of co-benefits result in double counting?

A. Decision Criteria

We begin with a discussion about the metrics used to judge the merits of alternative pollution policies. These are important because, as we will show, some of key questions and concerns raised about co-benefits are based on an appeal to different decision-making criteria. The first metric, taught in every Econ 101 course, is *efficiency*. In this context, efficiency requires the marginal benefit from abating a unit of each pollutant to equal the marginal cost. While often the focus of conceptual discussions of pollution control policy, efficiency is rarely the metric by which policies are judged in practice. Establishing efficiency is a high bar, as it requires identifying and monetizing the incremental benefits and costs of regulating each pollutant.

A second, less strict metric is *cost-effectiveness*, which is met when a given policy goal is achieved at least cost. The policy goal might be defined in terms of achieving an arbitrary regulated amount of pollution reduction or in terms of the monetary social benefits of pollution. Either way, cost-effectiveness is a weaker metric than efficiency. All efficient policies are cost-effective, but cost-effective policies are not necessarily efficient. Relative to efficiency, cost-effectiveness is easier to evaluate because it does not require knowing the incremental benefit of abating pollution. OMB (2003) Circular A-4 recommends that cost-effectiveness analysis, in addition to BCA, be used to support major rulemakings.

Finally, the criterion used implicitly by most federal agencies and the one informed by BCA, is *positive net benefits*—that is, do the benefits of a policy exceed its costs? Having positive net benefits guarantees neither efficiency nor cost-effectiveness. While all efficient policies have positive net benefits, policies with positive net benefits are not necessarily efficient. Alternatively, policies can minimize the cost- of achieving a policy goal while incurring negative net benefits, or can have positive net benefits but fail to minimize the costs of achieving a policy goal.

B. The Setup

Consider two pollutants, a target pollutant, denoted pollutant 1, and a co-pollutant, denoted pollutant 2. Pollutant 1 is the direct focus of a particular regulatory action, a policy, while pollutant 2 is secondary.⁹ Each pollutant can be reduced through costly investments in abatement (e.g., fuel switching, installing abatement equipment). Abatement functions map investments in abatement into units of pollution reduction. Suppose there are two abatement activities and let x_i denote investment in abatement activity $i = 1,2$. The quantity of each pollutant ultimately reduced or the level of abatement, denoted a_1 and a_2 , depends on investments in abatement activities. To simplify the intuition (and the math), we denominate the abatement activities x_1 and x_2 in units of pollution abated—the same units as a_1 and a_2 .

To capture the idea of co-benefits, we assume that abatement activity 1 is a more direct means of abating pollutant 1, but has some spillover benefits in the form of reduction in pollutant 2. The reverse is true for abatement activity 2—it is the most direct mechanism for abating pollutant 2 but also abates pollutant 1. We write these abatement functions as

$$a_1 = x_1 + \gamma_2 x_2 \quad \text{and} \quad a_2 = x_2 + \gamma_1 x_1, \tag{1}$$

where the γ 's are both less than one and greater than zero. A one unit increase in x_1 yields one fewer units of pollutant 1 as well as γ_1 fewer units of pollutant 2. Similarly, when x_2 increases by one unit, abatement of pollutant 2 increases by one unit and abatement of pollutant 1 increases by γ_1 units.

Figure 1 depicts this basic setup. Investments x_1 and x_2 are represented on the two axes. Abatement and benefits are increasing to the northeast, as are costs. An iso-cost curve $C(x_1, x_2)$ shows all the combinations of investments x_1 and x_2 that lead to the same cost, \bar{C} . Because we denominate the

⁹ That is, the numbering indicates a pollutant's relative centrality to the particular regulation's intended goal, not necessarily to the timing of regulation. Later in this section, we consider the important case of when co-pollutant 2 has already been regulated, and EPA is analyzing the net benefits of regulating target pollutant 1.

investments in pollution abated, the marginal costs of abating each pollutant using investments x_1 and x_2 are increasing. This leads to a convex iso-cost curve as depicted in Figure 1.

Figure 6: Cost-effective compliance using two activities (x_1 and x_2) with a regulation on one target pollutant ($a_1 \geq k_1$)

C. Policies

Now consider a policy that mandates a particular amount of abatement for the target pollutant a_1 at some arbitrary level k_1 . Note that the target level of abatement can be achieved entirely by investment in abatement activity 1 ($x_1 = k_1$), entirely by investment in abatement activity 2 ($x_2 = k_1/\gamma_2$), or some linear combination of the two. The constraint on abatement of the target pollutant imposed by the policy is depicted as the straight line in Figure 1, corresponding to the equation $k_1 = x_1 + \gamma_2 x_2$.

The least costly way to comply with the regulation is represented by the lowest iso-cost curve tangent to this line. Depending on the shape of the iso-cost function, that could be at the corner solution using only x_1 , at the corner solution using only x_2 , or as depicted in the figure at an interior solution using some of both. The least-cost combination $(x_1(k_1), x_2(k_1))$ is by definition cost-effective.

In this example, compliance with regulation of the target pollutant in the least costly way also results in some abatement of the second pollutant. In particular,

$$a_2 = x_2(k_1) + \gamma_1 x_1(k_1). \tag{2}$$

Equation (2) results from plugging in the cost-minimizing values of x_1 and x_2 from Figure 1 into the abatement function for a_2 in equation (1). The abatement a_2 is a benefit of policy k_1 that targets pollutant 1—it would not have occurred absent the policy. The abatement of pollutant 2 arises from cost-effective compliance with the policy on pollutant 1 through investments in both abatement activities, x_1 and x_2 . Note that by equation (2), even with the corner solution at which $x_2(k_1) = 0$, there

would still be abatement of a_2 as long as γ_1 is positive. Abatement of the co-pollutant is a co-benefit only in the semantic sense that the regulatory policy goal was to reduce pollutant 1.

Any policy requiring $a_1 \geq k_1$ that passes a BCA while ignoring those co-benefits would also pass a BCA considering those co-benefits. Nevertheless, some policies that would fail a BCA ignoring co-benefits would pass a BCA once co-benefits are considered. Moreover, in some cases, co-benefits alone may be sufficient for a policy to pass a BCA. Of course, as discussed above, passing a BCA does not mean that a policy is efficient or even cost-effective. This raises one of the chief criticisms of counting co-benefits—that if they are important, they should be regulated directly.

D. Targeting Co-Pollutants Directly

Concerns about co-benefits often focus on questions related to cost-effectiveness. For example, when commenting on the MATS rule, Dudley (2012) writes “If (PM_{2.5} co-benefits) are legitimate, certainly confronting them directly would achieve PM_{2.5} reductions more *cost-effectively* [emphasis added] than going after them indirectly using statutory authority designed to reduce toxic air pollutants” (p. 173). Smith (2011) writes “PM_{2.5}-related benefits would be more certain and more *cost-effectively* [emphasis added] obtained through a different regulation altogether than an air toxics rule” (p. 14) The same ideas underlie the EPA’s new recommendations in its *Guidelines* (discussed above) for the conduct of additional analyses of alternative policies that directly target ancillary impacts when co-benefits are significant.

Figure 7: Cost savings that arise from directly targeting the co-benefits, but ignoring reductions in the originally targeted pollutant

To address this critique, suppose the regulatory goal were to regulate pollutant 2 directly with the target of achieving at least as much abatement as resulted indirectly from the policy targeting pollutant 1. This would require a policy a_2 that satisfies $a_2 \geq k_2 = x_2(k_1) + \gamma_1 x_1(k_1)$ as in equation (2). As earlier, this

target level of abatement for pollutant 2 can be met by any linear combination of x_1 and x_2 , depicted by the new line added to Figure 2, which corresponds to the equation $k_2 = x_2 + \gamma_1 x_1$.

Because the new policy rule is designed to meet the same level of reduction in pollutant 2 achieved by the original policy, it must go through the original cost-minimizing point for compliance with k_1 . Note that one way to comply with the new policy is to do exactly the same thing that complied with the original policy. But the slope of the new k_2 policy is less steep than the slope of the original k_1 policy, because $-\gamma_1 > -1/\gamma_2$. As shown in the figure, the line representing the new policy necessarily passes below portions of the iso-cost curve that is tangent to the original k_1 line. This means that a different, lower iso-cost curve, representing smaller investments in x_1 and x_2 , could achieve the same level of abatement for pollutant 2 at lower cost than \bar{C} .

But, importantly, the costs savings does not come for free. The achievement—abating pollutant 2 by an amount equal to the co-benefits from targeting pollutant 1—comes at the cost of reduced abatement of pollutant 1. In Figure 2, there are no points along the line k_2 where both the original pollutant 1 regulation is met (above k_1) and costs are reduced (below \bar{C}). Therefore, the argument against co-benefits (“wouldn’t it be better to target them directly?”) works *only if* we ignore the broader benefits of abating the target pollutant. In this case of the policy targeting pollutant 2, abatement of pollutant 1 arises as a co-benefit due to the same connected abatement activities that resulted in reductions in pollutant 2 originally.

To put it bluntly, the argument against considering co-benefits holds only if we ignore co-benefits

E. Pre-Existing policies

We have focused so far on examples in which no pre-existing policies regulate either pollutant. With no pre-existing policies, benefits are never double counted. Nevertheless, another argument related to the treatment of co-benefits in BCA relates to the potential for double counting in the presence of pre-existing policies. For example, Gray (2015) argues that “whenever EPA counts PM_{2.5} or ozone reductions in its cost-benefit analysis for other rules, it is double-counting reductions already mandated...” (p. 32).

To examine this concern, we add a pre-existing policy targeting pollutant 2, such that abatement must be at least as large as $\bar{k}_2 = \gamma_1 x_1 + x_2$. Figure 3 depicts this case. Note that the pre-existing policy can be met with any level of $a_2 \geq \bar{k}_2$ and does not imply a specific level of abatement as in the previous section. Least-cost compliance with the pre-existing policy on a_2 occurs at point A in the figure. The associated cost is $C(x_1(\bar{k}_2), x_2(\bar{k}_2))$.

Figure 8: The effect of a pre-existing policy on the possibility, or lack thereof, of co-benefits

In the presence of the pre-existing policy on pollutant 2, consider a new policy that will target pollutant 1. Will this lead to co-benefits or co-costs associated with changes in the abatement of pollutant 2? The answer turns out to depend on the stringency of the new policy, the technology parameters (γ_1 and γ_2), and the cost functions. Figure 3 depicts several possibilities.

The first case is trivial, and arises if the new policy, k'_1 in Figure 3, is non-binding. In this example, compliance with the original policy \bar{k}_2 already led to abatement of the first pollutant, a_1 , sufficient to comply with the new regulation. There were, in a sense, reverse co-benefits generated from reductions in a_1 due to compliance with the pre-existing \bar{k}_2 policy, and these reductions were more than sufficient to meet compliance with the k'_1 policy. Polluters therefore need to make no changes, and cost minimization remains at point A in the figure. The new policy k'_1 has no benefits or costs.

The more interesting case arises if the new policy binds, as in k''_1 in Figure 3. Here compliance with the new policy must increase costs, as the original point A is insufficient to comply with the new policy targeting pollutant 1. Within this case there are two possibilities: an interior solution and a corner solution. In the first, depicted as point B, polluters must over-comply with the original policy \bar{k}_2 in order to meet the new k''_1 policy. Compared to point A, abatement of both pollutants is higher at point B so benefits are also higher. The increase in a_1 generates the target pollutant benefits from the new policy, and the new and additional increase in a_2 represents co-benefits.¹⁰

¹⁰ Note that this assumes the benefits can be added together, or “additive separability,” which is an implicit assumption typical of EPA regulatory analyses.

In the corner-solution case, represented by point C, there are no co-benefits. Polluters exactly comply with both policies. They comply with the original policy \bar{k}_2 in a less cost-effective way, by increasing x_1 and decreasing x_2 , but in doing so comply with the new rule k_1'' . Emissions of pollutant 2 simply remain at the level originally mandated under the policy \bar{k}_2 , by adjusting investments in the two abatement activities. Without accounting for these adjustments, double counting would be a concern, and we return to the subject again later, but first discuss the possibility for the relevant adjustments.

F. Regulatory Rebound

A more nuanced criticism of counting co-benefits on par with benefits associated with the directly targeted pollutant relates to what Fowlie et al. (2020) call “regulatory rebound.” The argument is that when there is a pre-existing regulation limiting the level of emissions of pollutant 2, a new policy that indirectly generates reductions in pollutant 2 when it targets reductions in pollutant 1, can induce a regulatory response that permits an increase in the level of pollutant 2 back to the originally mandated level. In the previous discussion, this possibility was unlikely, except in the corner-solution case, because we assumed the two abatement activities generate reciprocal co-benefits, that is, both γ_1 and γ_2 were assumed to be greater than zero. If co-benefits are not reciprocal, then there are two additional possibilities to explore: $\gamma_2 = 0$ or $\gamma_1 = 0$. We start with the first.

Suppose $\gamma_2 = 0$ and $0 < \gamma_1 < 1$ so that investments in abatement activity 1 reduce emissions of pollutant 2 (in addition to pollutant 1) but investments in abatement activity 2 reduce only emissions of pollutant 2. Also suppose there is a pre-existing policy on pollutant 2 so that $a_2 \geq \bar{k}_2$. Since $a_2 = \gamma_1 x_1 + x_2$, the policy constraint is just a sloped line as before, depicted in the left panel of Figure 4. Cost-minimizing compliance with the \bar{k}_2 is depicted as $(x_1(\bar{k}_2), x_2(\bar{k}_2))$. If the regulator now adds a new policy targeting pollutant 1 and denoted as k_1 , then the associated constraint can be represented by a vertical line as in the figure, because $\gamma_2 = 0$. The new policy effectively mandates a minimum level of x_1 , investment in abatement activity 1. Complying with the new k_1 policy involves higher costs, less x_2 and more x_1 , but no additional abatement of pollutant 2 (i.e., $a_2 = \bar{k}_2$ as before). In this case, there are no co-benefits. Polluters merely comply with the new policy k_1 in a way that increases the cost of meeting the pre-existing policy k_2 , but that generates the same amount of reduction in pollutant 2. Compliance costs from the new policy k_1 are represented in the graph by the difference between the two cost curves while the new policy’s benefits arise from the increase in a_1 . This is 100 percent regulatory rebound and is a special case of the corner solution depicted as point C in Figure 3 above, which occurs if the new policy k_1 is sufficiently low. If instead the new policy constraint were to the right of the horizontal intercept, there would be co-benefits.

Figure 9: Special cases with pre-existing policies: Case 1 is 100% regulatory rebound with increased costs and no co-benefits; Case 2 is increased costs and either co-benefits (point B) or 100% regulatory rebound and no co-benefits

For completeness, examine the alternative scenario with no co-benefits from the target pollutant to the previously-regulated pollutant ($\gamma_1 = 0$), but reverse co-benefits from the previously regulated pollutant to the target pollutant ($0 < \gamma_2 < 1$). This case is depicted in the right-hand panel of Figure 4. Here, the pre-existing policy \bar{k}_2 is represented as a horizontal line; because $\gamma_1 = 0$ the pre-existing policy targeting pollutant 2 effectively mandates a minimum level of x_2 . Complying with the pre-existing policy involves a corner solution, where $x_1 = 0$. When the new policy targeting abatement of pollutant 2 is added such that $a_1 \geq k_1$, then cost-minimizing compliance involves increasing x_1 but not necessarily increasing x_2 . First consider point C, which depicts one possibility—cost minimizing compliance with no increase in x_2 or a_2 . This is another special case of the corner solution depicted as point C in Figure 3 in the section on pre-existing policies, above.

Now consider point B, which represents the cost-minimizing compliance outcome at the tangency between the dashed iso-cost curve and the new policy k_1 (above the \bar{k}_2 constraint). In this case, the new policy k_1 yields over-compliance with the pre-existing policy \bar{k}_2 , and therefore co-benefits, as in the interior solution depicted as point B in Figure 3 earlier. Indeed, Figure 4 contains nothing more than two exaggerated examples of what happens in Figure 3. In Figure 4, as in all the figures, the \bar{k}_1 policy line is steeper than the \bar{k}_2 policy line, by the assumption that $0 < \gamma_1, \gamma_2 < 1$.

In sum, when we add a policy targeting pollutant 1 in the presence of a pre-existing policy that targets pollutant 2, there are three possible outcomes. The new policy is 1) moot, and there are no benefits or co-benefits (point A in Figure 3); 2) a corner solution with no co-benefits (point C in Figure 4); or 3) an interior solution with co-benefits (point B in Figure 4). Exaggerating Figure 3 so that the k_1 line is completely horizontal or the \bar{k}_2 line vertical makes no difference. We still get one of the three possible outcomes.

G. Double Counting

Returning now to the question: Does considering co-benefits amount to double counting? In some cases, the concern is that the EPA does not follow its own guidelines, which stipulate that baselines for RIAs must assume full compliance with all previously enacted rules, even if those rules have not yet been implemented or complied with (EPA 2014). In other cases, however, critics seem to presume that any consideration of co-benefits would represent double-counting.

Our analysis addresses both concerns. Any analysis that ignores a previous policy and assumes that all reductions in pollution stem from compliance with a new policy, will double-count benefits already counted in a BCA for the original policy. That is why we consider co-benefits to be zero at points A and C in Figure 3, in Case 1 in Figure 4, and in the corner solution of Case 2 in Figure 4. In some of these cases, an important mechanism to recognize is the regulatory rebound. Even if the new policy initially reduces a co-pollutant, adjustments in compliance to a pre-existing existing policy may be such that actual co-pollutant levels do not change after those adjustments take place. But if the original benefits were already counted, double counting would result.

At the same time, co-benefits represent true benefits when they result in over-compliance with the original rule, as in point B in Figure 3 or the dashed interior solution in Case 2 in Figure 4. Not considering those co-benefits would represent undercounting, not double counting.

5. Discussion and Conclusion

This paper considers the treatment of co-benefits in BCAs, with a particular focus on federal air quality regulations, for which questions and concerns about the role of co-benefits have been gaining momentum. Using a comprehensive dataset on all economically significant CAA rules issued by the EPA over the period 1997-2016, we show several trends and patterns. First, co-benefits make up a significant share of the monetized benefits in EPA RIAs over this period. Second, among the categories of co-benefits, those associated with reductions in adverse health effects due to fine PM are the most significant. Third, the inclusion of co-benefits has been critical in the majority of RIAs for making the determination in prospective analyses that the monetized benefits of the rule exceed the costs.

Are these findings cause for concern? We find that, in general and from a welfare economics perspective, the answer is no. We develop a simple conceptual framework to illustrate a critical point: co-benefits are simply a semantic category of benefits that should be included in BCAs in order to make an appropriate determination about whether a given policy promotes economic efficiency compared to a baseline status quo. Indeed, this finding is not novel and is covered in standard textbook treatments of best-practice for BCAs (e.g., Boardman et al. 2018).

More novel is our consideration of specific questions and concerns about co-benefits that have been raised in the context of CAA rules. The first that if co-benefits are large, wouldn't regulating them directly be more efficient or cost-effective? Our answer to this question is that it is possible that a given level of co-benefits could be achieved more cost-effectively by targeting the co-pollutant directly, but importantly, the direct policy is not necessarily a more efficient alternative. In fact, we show that this line of argument against considering co-benefits depends on a tautology, whereby it holds generally

only if one starts with the proposition that we should ignore co-benefits. The argument also relies on the questionable starting point that a proposed regulation for one pollutant can be replaced by one for another. While possible in theory, the idea does not square with the required statutory basis for most CAA regulations.

The second question relates to how we should count co-benefits if the co-pollutant is already subject to a pre-existing regulation. In this case, we show how care needs to be taken to measure only those benefits that are the incremental consequence of the policy under consideration. But these challenges are the same as those that arise more generally when seeking to identify the most appropriate baseline for analysis, and they are not unique to the estimation of co-benefits. In doing so, however, particular attention should be given to the potential for regulatory rebound, that is, the policy under consideration may shift behaviors related to compliance with another policy that targets the co-pollutant. Taking account of these effects will avoid the possibility for double counting.

We conclude with some observations about the political economy underlying why it appears that co-benefits are an increasing topic of debate, notwithstanding how the questions are relatively “settled science” from the perspective of how to conduct BCAs. First, it is important to recognize that in practice BCAs rarely (if ever) quantify and monetize all of the expected benefits and costs of an action. While the science and methods of valuation continue to advance, there are many categories of benefits that are exceedingly difficult or impossible to estimate. Estimating more categories of benefits also takes time and resources, which are often scarce. It is nevertheless sufficient to show that a subset of the benefits, which may arise entirely from co-benefits, are greater than the costs to conclude that a regulation has positive net benefits. This aim in itself can explain why co-benefits have become increasingly important. Research and the development of best practices tend to focus on the impacts that have the greatest value, and the health benefits of reducing fine PM appear to be dramatically larger than the health impacts of cutting other air pollutants. Since the Clean Air Act does not require – and in some cases explicitly prohibits consideration of – BCA to inform the setting of air quality standards and regulations, the value of the information in an RIA lies in its communication to the public, key stakeholders, and Congress. For many consumers of this information, once EPA has demonstrated that the monetized benefits exceed the monetized costs, the value of incremental information on other benefits becomes quite low.

This distinction between the quantified, monetized benefits and the true total benefits means that there are two possible interpretations of our findings. It could be that co-benefits truly make up a large part of the actual total social benefits. Alternatively, it could be that co-benefits just happen to be easier for the EPA to monetize, and so make up a large share of the quantified, monetized benefits reported in RIAs.

Finally, let us observe a fundamental tension in the implementation of Federal regulatory policy as it pertains to the CAA. As noted above, for four decades the White House has directed regulatory agencies to adopt rules where the benefits justify or exceed the costs and to pursue, where feasible, regulatory options that maximize net social benefits. Since 2017, however, the Trump Administration has focused on the costs of regulations, both through a “regulatory budget” that effectively places limits on the incremental costs new rules can impose on society (regardless of net social benefits) and in its deregulation agenda (CEA 2019). With virtually every Clean Air Act regulation since 1997 estimated to

deliver monetized benefits in excess of monetized costs (see Figure 2), the removal of any of these rules through deregulatory actions would impose social costs in excess of the benefits. Casting doubt on the applicability or validity of fine PM benefits, by questioning the appropriateness of including co-benefits, could enable a regulator to pursue actions that reduce regulatory costs without appearing to impose net social costs. But for reasons we have discussed, this conclusion would be wrong.

7. Appendix

Table A-1. List of Major Clean Air Act Regulations Compiled from OMB Reports to Congress, 1997-2020

RIN	Rule	Date Issued	Federal Register
2060-AF76*	Control of Emissions of Air Pollution from Highway Heavy-Duty Engines	10/21/1997	62 FR 54694
2040-AB53	National Emission Standards for Hazardous Air Pollutants for Source Category: Pulp and Paper Production; Effluent Limitations Guidelines, Pretreatment Standards, and New Source Performance Standards: Pulp, Paper, and Paperboard Category	4/15/1998	63 FR 18504
2060-AD33*	Emission Standards for Locomotives and Locomotive Engines	4/16/1998	63 FR 18978
2060-AF76_98*	Control of Emissions of Air Pollution From Nonroad Diesel Engines	10/1/1998	63 FR 56968
2060-AH10	Finding of Significant Contribution and Rulemaking for Certain States in the Ozone Transport Assessment Group Region for Purposes of Reducing Regional Transport of Ozone	10/27/1998	63 FR 57356
2060-AE29*	Phase 2 Emission Standards for New Nonroad Spark-Ignition Nonhandheld Engines At or Below 19 Kilowatts	3/30/1999	64 FR 15208
2060-AF32	Regional Haze Regulations	7/1/1999	64 FR 35714
2060-AI23	Control of Air Pollution From New Motor Vehicles: Tier 2 Motor Vehicle Emissions Standards and Gasoline Sulfur Control Requirements	2/10/2000	65 FR 6698
2060-AE29_00*	Phase 2 Emission Standards for New Nonroad Spark-Ignition Handheld Engines At or Below 19 Kilowatts and Minor Amendments to Emission Requirements Applicable to Small Spark-Ignition Engines and Marine Spark-Ignition Engines	4/25/2000	65 FR 24268
2060-AI12*	Control of Emissions of Air Pollution from 2004 and Later Model Year Heavy Duty Highway Engines and Vehicles; Revision of Light-Duty On-Board Diagnostics Requirements	10/6/2000	65 FR 59896
2060-AI69	Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards and Highway Diesel Fuel Sulfur Control Requirements	1/18/2001	66 FR 5002
2060-AI11	Control of Emissions From Nonroad Large Spark-Ignition Engines, and Recreational Engines (Marine and Land-Based)	11/8/2002	67 FR 68242
2060-AG63	National Emission Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines	6/15/2004	69 FR 33474
2060-AK27	Control of Emissions of Air Pollution From Nonroad Diesel Engines and Fuel	6/29/2004	69 FR 38958

2060-AG69	National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters	9/13/2004	69 FR 55218
2060-AJ65	Standards of Performance for New and Existing Stationary Sources: Electric Utility Steam Generating Units	5/18/2005	70 FR 28606
2060-AJ31	Regional Haze Regulations and Guidelines for Best Available Retrofit Technology (BART) Determinations	7/6/2005	70 FR 39104
2060-AM82	Standards of Performance for Stationary Compression Ignition Internal Combustion Engines	7/11/2006	71 FR 39154
2060-AI44	National Ambient Air Quality Standards for Particulate Matter	10/17/2006	71 FR 61144
2060-AK70	Control of Hazardous Air Pollutants From Mobile Sources	2/26/2007	72 FR 8428
2060-AN24	National Ambient Air Quality Standards for Ozone	3/27/2008	73 FR 16436
2060-AN72	Standards of Performance for Petroleum Refineries	4/1/2008	73 FR 35838
2060-AM06	Control of Emissions of Air Pollution From Locomotive Engines and Marine Compression-Ignition Engines Less Than 30 Liters per Cylinder	5/6/2008	73 FR 25098
2060-AM34	Control of Emissions From Nonroad Spark-Ignition Engines and Equipment	10/8/2008	73 FR 59034
2060-AN83	National Ambient Air Quality Standards for Lead	11/12/2008	73 FR 66964
2060-AO79*	Mandatory Reporting of Greenhouse Gases	10/30/2009	74 FR 56260
2060-AP36	National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines	3/3/2010	75 FR 9648
2060-AO38	Control of Emissions of Air Pollution from Category 3 Marine Diesel Engines	4/30/2010	75 FR 22896
2060-AO48	Primary National Ambient Air Quality Standard for Sulfur Dioxide	6/22/2010	75 FR 35520
2060-AQ13	Existing Stationary Spark Ignition RICE NESHAP	8/1/2010	*
2060-AO15	Amendments to the National Emission Standards for Hazardous Air Pollutants and New Source Performance Standards (NSPS) for the Portland Cement Manufacturing Industry	9/9/2010	75 FR 54970
2060-AP50	Federal Implementation Plans: Interstate Transport of Fine Particulate Matter and Ozone and Correction of SIP Approvals	8/8/2011	76 FR 48208
2060-AP61	Greenhouse Gas Emissions Standards and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles	9/15/2011	76 FR 57106
2060-AP76*	Final New Source Performance Standards and Amendments to the National Emissions Standards for Hazardous Air Pollutants for the Oil and Natural Gas Industry	4/1/2012	*
2060-AN72_12	Standards of Performance for Petroleum Refineries; Standards of Performance for Petroleum Refineries for Which Construction, Reconstruction, or Modification Commenced After May 14, 2007	9/12/2012	77 FR 56422
2060-AQ54	2017-2025 Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards	10/15/2012	77 FR 62624
2060-AO47	National Ambient Air Quality Standards for Particulate Matter	1/15/2013	78 FR 3086

2060-AQ58	National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines; New Source Performance Standards for Stationary Internal Combustion Engines	1/30/2013	78 FR 6674
2060-AR13	National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters	1/31/2013	78 FR 7138
2060-AQ86	Control of Air Pollution From Motor Vehicles: Tier 3 Motor Vehicle Emission and Fuel Standards	4/28/2014	79 FR 23414
2060-AP93	Standards of Performance for New Residential Wood Heaters, New Residential Hydronic Heaters and Forced-Air Furnaces	3/16/2015	80 FR 13672
2060-AQ91*	Standards of Performance for Greenhouse Gas Emissions From New, Modified, and Reconstructed Stationary Sources: Electric Utility Generating Units	10/23/2015	80 FR 64510
2060-AR33	Carbon Pollution Emission Guidelines for Existing Stationary Sources: Electric Utility Generating Units	10/23/2015	80 FR 64662
2060-AP69	NESHAP for Brick and Structural Clay Products Manufacturing; and NESHAP for Clay Ceramics Manufacturing	10/26/2015	80 FR 65470
2060-AP38	National Ambient Air Quality Standards for Ozone	10/26/2015	80 FR 65292
2060-AS30	Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources	6/3/2016	81 FR 35824
2060-AS23	Emission Guidelines and Compliance Times for Municipal Solid Waste Landfills	8/29/2016	81 FR 59276
2060-AS16	Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles— Phase 2	10/25/2016	81 FR 73478
2060-AS05	Cross-State Air Pollution Rule Update for the 2008 Ozone NAAQS	10/26/2016	81 FR 74504

Notes: In those cases in which EPA used the same RIN more than once, we have modified the second usage of the RIN by adding an extension that represent the two-digit year of rule promulgation. Those with an asterisk next to RIN number are those for which BCA number are not available because the RIA focused on cost-effectiveness for some other analytical approach.

8. Supplementary Information

Files that will be made available online are 1) Background information on how significant rules were determined in each year, 2) references and links to the OMB reports to Congress in which rules were identified; 3) a Dropbox folder that includes PDF documents for all rules and RIAs; and 4) an excel spreadsheet with the complete database.
