Introduction

- Poor health impacts individuals through several channels:

reduces labor productivity

increases costs of working, mortality risk, medical expenses

increases chance of access to social insurance programs (SSDI/SSI)

Introduction

- Poor health impacts individuals through several channels:
 - reduces labor productivity
 - increases costs of working, mortality risk, medical expenses
 - increases chance of access to social insurance programs (SSDI/SSI)
- Individuals in poor health have lower earnings and labor supply

Introduction

- Poor health impacts individuals through several channels:

 - reduces labor productivity

 - increases costs of working, mortality risk, medical expenses

 - increases chance of access to social insurance programs (SSDI/SSI)

- Individuals in poor health have lower earnings and labor supply

▶ graph

- **Question:** How important is health inequality for lifetime earnings inequality?

- What are key channels?

availability/generosity of Soc Ins – vs – higher costs/lower productivity of work

To answer these questions

1. Construct an objective measure of “health”

- frailty index: cumulative sum of past adverse health events

To answer these questions

1. **Construct an objective measure of “health”**

- frailty index: cumulative sum of past adverse health events

2. **Empirical Analysis:** dynamic panel estimation using PSID data

- estimate effect of health on current earnings
- assess impact of health on each margin: hours, wages, participation

To answer these questions

1. **Construct an objective measure of “health”**

- frailty index: cumulative sum of past adverse health events

2. **Empirical Analysis:** dynamic panel estimation using PSID data

- estimate effect of health on current earnings
- assess impact of health on each margin: hours, wages, participation

3. **Quantitative Analysis:** structural model consistent with empirical findings

- agents in the model have heterogeneous and risky health profiles
- use model to assess

impact of health inequality on lifetime earnings inequality

relative importance of each channel through which health operates

How we measure health

- **Frailty index:** cumulative sum of all adverse health events (*deficits*)
 - Proposed and widely used in gerontology literature.
- Type of deficit variables used to construct frailty index in PSID:
 - Difficulties with ADL and IADL (eating, dressing, using phone, etc)
 - Diagnosis (ever had heart disease, psychological problems, loss of memory, etc)
 - Body measurements (BMI over 30, etc)
- Assign value of 1 whenever one of these conditions exists, and value of 0 o/w.
- Add them up and normalize to a number between 0 and 1.

▶ gerontology literature

Why use frailty index?

1. Need objective measure of health to study health-contingent policies.
2. Easy to construct, univariate, and highly predictive of health-related outcomes: mortality, nursing home stay, DI reciprocity, medical expenditures. [▶ tables](#)
3. Better than self-reported health at predicting decline in health with age. [▶ illustration](#)
4. Measures health on finer scale. Important for observing variation in health in the unhealthy tail and its effects. [▶ graph](#)
5. Can be treated as continuous variable → useful for estimating marginal effects.
6. Consistent measure of health across multiple datasets: PSID, MEPS, HRS.

Summary Stats for Frailty

Sample: 2003–2017 PSID household heads + spouses, ages 25–94

Boxplots of frailty by age

Cross-sectional distribution

Mean	0.11	Median	0.07
<i>by gender:</i>		Standard deviation	0.11
male	0.11	<i>Wave-to-wave:</i>	
female	0.12	+ Δ frailty	0.29
<i>by education:</i>		- Δ frailty	0.13
HS dropouts	0.16		
HS grads	0.12	Effect of 1 additional deficit	+0.037
college grads	0.08		

- Mean frailty increases with age and decreases with education.

How we measure health

Empirical Analysis

Structural Model

Calibration Highlights

Quantitative Exercise

Empirical Analysis: Question

- What is the effect of health — measured by frailty — on earnings and what are the important margins?
- We estimate the following regression

$$y_{i,t} = b_i + \gamma f_{i,t} + \alpha_1 y_{i,t-1} + \alpha_2 y_{i,t-2} + \delta \mathbf{Z}_{i,t} + \varepsilon_{i,t}$$

using **Blundell-Bond System GMM estimator** and PSID sample (ages 25-64)

$y_{i,t}$ is log of earnings (or hours, or wages)

$\mathbf{Z}_{i,t}$ is vector of exogenous controls: marital status, marital status \times gender, # of kids, # of kids \times gender, cubic in age, and year dummies

Empirical Analysis: Question

- What is the effect of health — measured by frailty — on earnings and what are the important margins?
- We estimate the following regression

$$y_{i,t} = b_i + \gamma f_{i,t} + \alpha_1 y_{i,t-1} + \alpha_2 y_{i,t-2} + \delta \mathbf{Z}_{i,t} + \varepsilon_{i,t}$$

using **Blundell-Bond System GMM estimator** and PSID sample (ages 25-64)

$y_{i,t}$ is log of earnings (or hours, or wages)

$\mathbf{Z}_{i,t}$ is vector of exogenous controls: marital status, marital status \times gender, # of kids, # of kids \times gender, cubic in age, and year dummies

- Why dynamic panel?
 - Want fixed effects to control for unobserved heterogeneity.
 - Earnings and frailty are both highly persistent variables.
 - Concerns of endogeneity/simultaneity.

Empirical Analysis: Question

- What is the effect of health — measured by frailty — on earnings and what are the important margins?
- We estimate the following regression

$$y_{i,t} = b_i + \gamma f_{i,t} + \alpha_1 y_{i,t-1} + \alpha_2 y_{i,t-2} + \delta \mathbf{Z}_{i,t} + \varepsilon_{i,t}$$

using **Blundell-Bond System GMM estimator** and PSID sample (ages 25-64)

$y_{i,t}$ is log of earnings (or hours, or wages)

$\mathbf{Z}_{i,t}$ is vector of exogenous controls: marital status, marital status \times gender, # of kids, # of kids \times gender, cubic in age, and year dummies

- Report $\gamma/27$: response of earnings/hours to one more deficit.

No statistically significant effect of earnings on frailty

Note:

p* < 0.1; *p* < 0.05; ****p* < 0.01

Empirical Findings — Summary

- Increases in frailty reduce earnings and hours.
- The effect is
 - primarily driven by employment margin.
 - concentrated in less educated and less healthy individuals.
- These findings suggest that
 - health inequality may be an important source of lifetime earnings inequality.
 - social insurance may play an important role.
- To quantify the impact of health inequality on lifetime earnings inequality (and importance of various channels) we build a structural model.

Plan of the Talk

How we measure health

Empirical Analysis

Structural Model

Calibration Highlights

Quantitative Exercise

Quantitative Model Overview

- J period, OLG, GE model.
- Individuals are subject to exogenous shocks:
 - frailty, productivity, and job separation.
- If separated, can choose to pay a one-time wage cost and go back to work.
- Frailty impacts an individual's
 - Labor productivity
 - Mortality
 - OOP medical expenditures
 - Disutility of working
 - Probability of becoming DI beneficiary.

Quantitative Model Overview

- **Individuals:**
 - **Employed:**
 - If young: can choose to switch to non-employment.
 - If old: can choose to retire.
 - **Non-employed:**
 - Become a DI beneficiary with some probability.
 - Can choose to go to employed state.
 - **DI beneficiaries:**
 - Collect SSDI/SSI benefits until retirement at age R .
 - DI benefits have a guaranteed minimum (SSI).
 - **Retirees:**
 - Collect social security benefits and do not work.
- **Government:** collects taxes (capital, income, payroll)
 - Pays out SS, SSDI, SSI, and means-tested transfers + exogenous government purchases.

Problem of Young Employed Individual

Employed individual with $j < R - 1$ solves

$$V^E(x, i_s) = \max_{c, a' \geq 0} u(c, v(f)) + \sigma \beta p(j, f, s) E \left[\max \left\{ V^E(x', 1), V^N(x', 0) \right\} \right] \\ + (1 - \sigma) \beta p(j, f, s) E \left[\max \left\{ V^E(x', 0), V^N(x', 0) \right\} \right]$$

subject to ...

- individual state variable $x = (j, a, s, f, \epsilon, \bar{e})$

j : age

a : assets

s : education

f : frailty $\equiv \psi(j, s, \epsilon_f)$ where ϵ_f is frailty shocks and fixed effect

ϵ : productivity shock and fixed effect

\bar{e} : average past earnings

Problem of Young Employed Individual

Employed individual with $j < R - 1$ solves

$$V^E(x, i_s) = \max_{c, a' \geq 0} u(c, v(f)) + \sigma \beta p(j, f, s) E \left[\max \left\{ V^E(x', 1), V^N(x', 0) \right\} \right] \\ + (1 - \sigma) \beta p(j, f, s) E \left[\max \left\{ V^E(x', 0), V^N(x', 0) \right\} \right]$$

subject to

$$\frac{a'}{1+r} + c + m^E(j, f, s) = a + w\eta(j, f, s, \epsilon) - T(w\eta) - \chi(w\eta)i_s + Tr(x, i_s),$$

$$\bar{e}' = [(j-1)\bar{e} + w\eta]/j$$

- i_s : indicates the worker is coming from separation

Problem of Young Employed Individual

Employed individual with $j < R - 1$ solves

$$V^E(x, i_s) = \max_{c, a' \geq 0} u(c, v(f)) + \sigma \beta p(j, f, s) E \left[\max \left\{ V^E(x', 1), V^N(x', 0) \right\} \right] \\ + (1 - \sigma) \beta p(j, f, s) E \left[\max \left\{ V^E(x', 0), V^N(x', 0) \right\} \right]$$

subject to ...

- Utility function is

$$u(c, v(f)) = \frac{\left(c^\mu (1 - v(f))^{1-\mu} \right)^{1-\gamma}}{1 - \gamma},$$

where $v(f) = \phi_0 + \phi_1 f^{\phi_2}$, $\phi_0 \geq 0$, $\phi_1 \geq 0$, and $\phi_2 \geq 0$.

Problem of Old Employed Individual

Employed individual with $j > R - 1$ solves

$$V^E(x, i_s) = \max_{c, a' \geq 0} u(c, v(f)) + \sigma p(j, f, s) E \left[\max \left\{ V^E(x', 1), V^R(x') \right\} \right] \\ + (1 - \sigma) \beta p(j, f, s) E \left[\max \left\{ V^E(x', 0), V^R(x') \right\} \right]$$

subject to

$$\frac{a'}{1+r} + c + m^R(j, f, s) = a + w\eta(j, f, s, \epsilon) + SS(\bar{e}) - T(w\eta) \\ - \chi(w\eta)i_s + Tr(x, i_s),$$

$$\bar{e}' = \bar{e}$$

Problem of Young Non-employed Individual

Non-employed individual with $j < R - 1$ solves

$$V^N(x, n_a) = \max_{c, a' \geq 0} u(c) + \theta(f, n_a) \beta p(j, f, s) E \left[V^D(x', 0) \right] \\ + [1 - \theta(f, n_a)] \beta p(j, f, s) E \left[\max \left\{ V^E(x', 1), V^N(x', n_a + 1) \right\} \right]$$

subject to

$$\frac{a'}{1+r} + c + m^N(j, f, s) = a + Tr(x).$$

- n_a : number of periods in non-employment.
- Probability of successful DI application: $\theta(f, n_a) = \min \{1, \kappa_0 f^{\kappa_1} n_a^{\kappa_2}\}$

Problem of a DI Beneficiary

- DI beneficiary with $j < R - 1$ solves

$$V^D(x, n_d) = \max_{c, a' \geq 0} u(c) + \beta p(j, f, s) E \left[V^D(x', n_d + 1) \right]$$

subject to

$$\frac{a'}{1+r} + c + m^D(j, f, s, n_d) = a + SS(\bar{e}) + Tr(x, n_d).$$

- n_d : number of periods on DI.

How we measure health

Empirical Analysis

Structural Model

Calibration Highlights

Quantitative Exercise

Calibration Strategy Overview

- Model period is 1 year.
- Agents live from $j = 1$ (age 25) to a maximum $J = 70$ (age 94).
- Frailty affects earnings through five channels:

1. Survival rate
2. Out of pocket medical expenditures
3. Labor productivity – proxied by hourly wages
4. Probability of successful DI application
5. Preferences – disutility of work

} estimated outside model

} calibrated using model

Stochastic process for frailty

- Assume positive fraction of people with zero frailty at age 25.
- Each period, frailty remains zero with probability $P(\text{age})$ and becomes positive with probability $1 - P(\text{age})$.
- If positive, log frailty is sum of
 - **deterministic component:** age poly
 - **stochastic component:** fixed effect, transitory shock, and AR(1) shock
- Estimate separately for each education group.
- To account for selection due to mortality, estimation uses
 - auxiliary simulation model
 - simulated method of moments

Stochastic frailty process for high school graduates

Fraction w/zero frailty

Mean log frailty age-profile (deterministic component targets)

Variance-covariance moments (stochastic component targets)

Stochastic frailty process for high school graduates

Fraction w/zero frailty

Mean log frailty age-profile
(deterministic component targets)

Variance-covariance moments
(stochastic component targets)

- **Important to account for selection:** effects of mortality on mean and variance of log frailty are large at older ages.

Stochastic process for productivity

- By education, log productivity (wage) is sum of
 - **deterministic component**: age poly and **quadratic frailty effect**
 - **stochastic component**: fixed effect and AR(1) shock
- Frailty effects are estimated using dynamic panel system GMM estimator.
- Correct for selection bias using a procedure recommended by Al-Saddoon et al. (2019).
- Effect of an additional deficit on wage:

	HSD	HSG	COL (frailty < 76th prctile)	COL (frailty = 95th prctile)
Before correction	-4.2%	-2.5%	0%	-2.6%
After correction	-4.4%	-2.7%	0%	-2.8%

Capturing severe disability

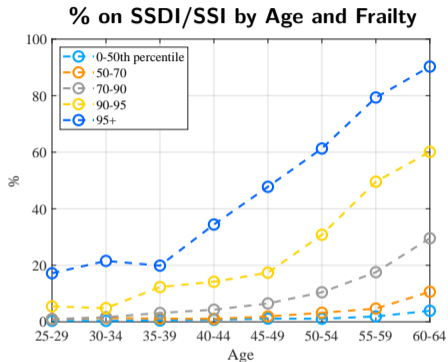

- Productivity process estimation doesn't capture the effects of severely working-limiting lifelong disability.
- To capture these effects we assume:
 - individuals face small probability of being born severely disabled (having zero productivity)
 - probability depends on frailty and education
 - pinned down by the fractions of 25 year-olds on SSI/SSDI in the data (2.3% overall)

Disutility of Work vs DI Probabilities

Identification Strategy

- DI probability and disutility of work parameters calibrated using the model.
- Calibration targets:
 - DI reciprocity rates by age and frailty for ages 25 to 64.
 - Labor force participation by age and frailty for ages 25 to 74.
 - Relative DI acceptance rate by year since initial application.
- **Idea:** DI process does not directly affect labor supply after age 65.
 - Dispersion in LFPR's by frailty for 65-74 year-olds pins down frailty effect on work disutility.

DI and LFP by Age and Frailty: Model vs Data

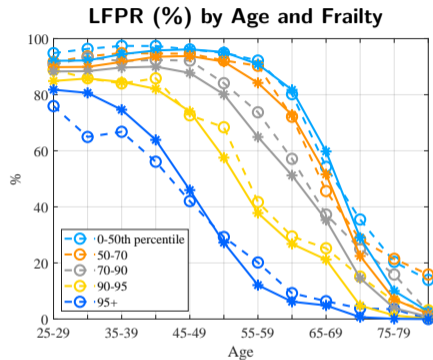

Data source: MEPS 2000–2016 and SSA.

Data source: 2003–2015 PSID men ages 25-84.

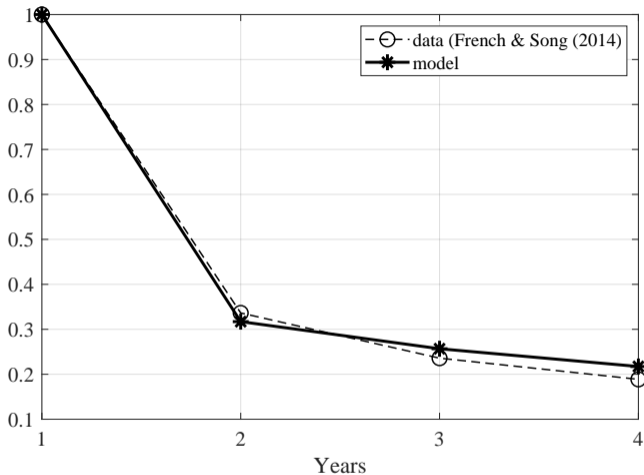

- Target more moments in the unhealthy tail of frailty distribution.

DI and LFP by Age and Frailty: Model vs Data

- Target more moments in the unhealthy tail of frailty distribution.
- Model matches moments well including the dispersion in LFPR's by frailty for 65-74 year-olds.

DI acceptance rate: Model vs. Data

Data source: French and Song (2014)

- Model also matches rate of decline in DI acceptance by year since initial application

Calibrated Values

Table: DI Probability and Disutility Parameter Values

Parameter	Description	Value
κ_0	level	198
κ_1	elasticity w.r.t. frailty	5.7
κ_2	elasticity w.r.t. 'number of attempts'	0.6
ϕ_0	level	0.7
ϕ_1	frailty level effect	3.9
ϕ_2	elasticity w.r.t frailty	5.4

- DI probability $\theta(f, n_a) = \min \{1, \kappa_0 f^{\kappa_1} n_a^{\kappa_2}\}$ increases in frailty and increases in number of years since initially applied.
- Disutility from working $v(f) = \phi_0 + \phi_1 f^{\phi_2}$ is increasing and convex in frailty.

How we measure health

Empirical Analysis

Structural Model

Calibration Highlights

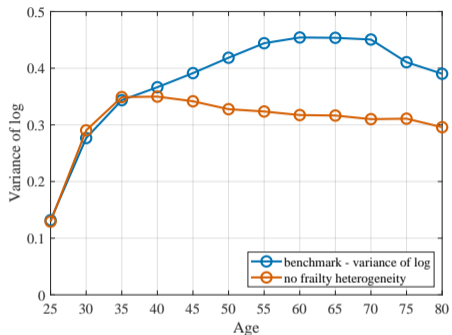

Quantitative Exercise

Quantitative Exercise

- To understand the impact of health inequality on lifetime earnings inequality:
 - Consider a counterfactual economy where everyone has the same (average) frailty profile.
 - What is the impact on lifetime earnings inequality?

lifetime earnings at each age = sum of all earnings up to that age

Lifetime earnings inequality by age: Variance of log

	Age 45	Age 55	Age 65	Age 75
Benchmark	0.391	0.444	0.454	0.411
No frailty heterogeneity	0.342	0.324	0.316	0.311
$\Delta \downarrow$	12.7%	27.1%	30.2%	24.3%

Quantitative Model Results: Decomposition

- How important are each of the 5 channels through which health affects individuals?
 1. Probability of getting DI
 2. Labor productivity
 3. Disutility
 4. Medical expenses
 5. Survival probability
- To assess the importance of each channel:
 - Run 5 counterfactuals
 - Counterfactual 1: Equivalent to baseline except probability of DI is determined by average frailty profile.
 - And so on...

Computational Experiments: Decomposition

Table: Effect of removing frailty variation in each channel on the variance of log lifetime earnings

	age 45	age 55	age 65	age 75
1. DI channel	↑ 0.0%	↓ 14.0%	↓ 20.9%	↓ 19.8%
2. Labor prod channel	↓ 2.2%	↓ 3.6%	↓ 4.1%	↓ 4.4%
3. Disutility channel	↓ 0.4%	↓ 0.8%	↓ 1.0%	↓ 0.9%
4. Med exp channel	↓ 0.1%	↓ 0.1%	↓ 0.0%	↑ 0.1%
5. Surv prob channel	↓ 0.9%	↑ 0.2%	↑ 8.2%	↑ 5.8%

- These three channels are least important.

Computational Experiments: Decomposition

Table: Effect of removing frailty variation in each channel on the variance of log lifetime earnings

	age 45	age 55	age 65	age 75
1. DI channel	↑ 0.0%	↓ 14.0%	↓ 20.9%	↓ 19.8%
2. Labor prod channel	↓ 2.2%	↓ 3.6%	↓ 4.1%	↓ 4.4%
3. Disutility channel	↓ 0.4%	↓ 0.8%	↓ 1.0%	↓ 0.9%
4. Med exp channel	↓ 0.1%	↓ 0.1%	↓ 0.0%	↑ 0.1%
5. Surv prob channel	↓ 0.9%	↑ 0.2%	↑ 8.2%	↑ 5.8%

- Removing DI channel increases inequality at younger ages and decreases it at older ages.

Computational Experiments: Decomposition

Table: Effect of removing frailty variation in each channel on the variance of log lifetime earnings

	age 45	age 55	age 65	age 75
1. DI channel	↑ 0.0%	↓ 14.0%	↓ 20.9%	↓ 19.8%
2. Labor prod channel	↓ 2.2%	↓ 3.6%	↓ 4.1%	↓ 4.4%
3. Disutility channel	↓ 0.4%	↓ 0.8%	↓ 1.0%	↓ 0.9%
4. Med exp channel	↓ 0.1%	↓ 0.1%	↓ 0.0%	↑ 0.1%
5. Surv prob channel	↓ 0.9%	↑ 0.2%	↑ 8.2%	↑ 5.8%

- Removing DI channel increases inequality at younger ages and decreases it at older ages.
- Removing productivity channel reduces lifetime earnings inequality at all ages.

LFP of Highly Frail in Counterfactual Economies

- Without DI channel:

- Frail individuals no longer qualify for SSDI w/ high probability \Rightarrow Highly frail old's LFP \uparrow
- Less incentive to work to accumulate SSDI earnings credits \Rightarrow Highly frail young's LFP \downarrow .

LFP of Highly Frail in Counterfactual Economies

- Without productivity channel:
 - Wages of frail individuals $\uparrow \Rightarrow$ Highly frail LFP \uparrow at all ages.

Welfare effects of eliminating the SSDI program

- SSDI/SSI is primary channel through which health inequality leads to \uparrow lifetime earnings inequality. Should we eliminate it?

Welfare effects of eliminating the SSDI program

- SSDI/SSI is primary channel through which health inequality leads to \uparrow lifetime earnings inequality. Should we eliminate it?
- No, removing DI program reduces ex-ante welfare.

Ex-ante welfare changes (% of lifetime consumption)				
	Average	HSD	HSG	COL
No DI program (PE) no benefits or DI payroll taxes	-1.15%	-3.13%	-1.80%	0.74%
No DI program (GE), prop. increase in income taxes	-1.79%	-3.69%	-2.44%	0.05%
No DI program (GE), reduction of consumption floor	-2.49%	-5.80%	-3.21%	0.09%

Conclusion

- Document empirically:
 - Large response of earnings to incremental changes in frailty: mostly driven by participation.
 - Wage effects for less educated workers.
- Results from structural model:
 - Health inequality accounts for approximately 30% of lifetime earnings inequality at age 65.
 - Reduced participation due to increased access to SSDI when health is poor plays an important role.
 - Yet, SSDI program is ex-ante welfare improving.

The End

Thank You!

Plan of the Talk

back up

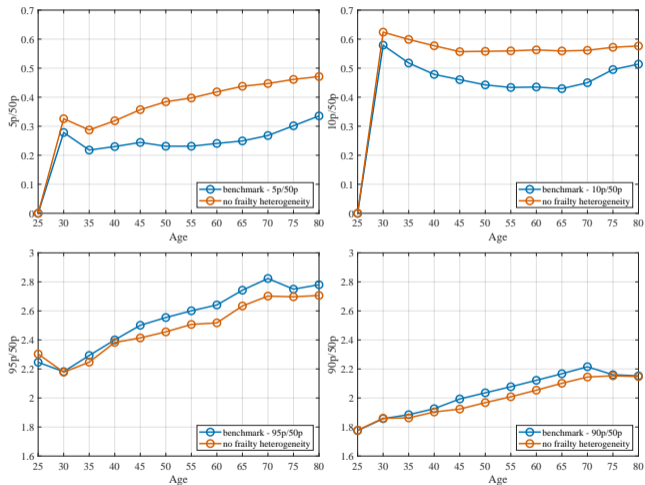

Back Up Slides

Fraction at zero: Model vs Data

- Removing frailty heterogeneity also reduces the fraction with zero lifetime earnings.

Lifetime earnings inequality by age: Ratios

- Impact is concentrated in the bottom of the lifetime earnings distribution.

Quantitative Model Results

Lifetime earnings inequality by age: Gini

- Removing frailty heterogeneity reduces the Gini of lifetime earnings at age 65 by 8.5%.

Lifetime earnings inequality by age: Variance decomposition

Contribution of Ex-ante Heterogeneity vs. Frailty Shocks				
	Age 45	Age 55	Age 65	Age 75
Benchmark	0.391	0.444	0.454	0.411
No frailty heterogeneity $\Delta \downarrow$	0.342 12.7%	0.324 27.1%	0.316 30.2%	0.311 24.3%
No frailty fixed effect $\Delta \downarrow$	0.351 10.2%	0.391 12.0%	0.393 13.4%	0.368 10.4%
No frailty shock $\Delta \downarrow$	0.340 13.1%	0.341 23.3%	0.353 22.2%	0.350 14.8%

- Health shocks account for $\approx 2/3$'s of the impact of health inequality on lifetime earnings inequality.
- Removing heterogeneity vs risk vs both impacts both amount and timing of lifecycle labor supply.

Removing heterogeneity vs shocks vs both: Fraction employed

- No fixed effect, shocks, or both: lifetime labor supply $\uparrow \Rightarrow$ lifetime earnings inequality \downarrow
- No fixed effects **and** no shocks: labor supply of young $\downarrow \Rightarrow$ lifetime earnings inequality \uparrow
- No fixed effects **or** no shocks: labor supply of young $\uparrow \Rightarrow$ lifetime earnings inequality \downarrow

LFP in Counterfactual Economies

- LFP effects of removing frailty inequality are very small in healthy half of distribution.
- Without DI channel: LFP is lower at young ages and higher at older ages.
- Without productivity channel: LFP of highly frail is higher at all ages.

Alternative measures of inequality: Variance of log

Lifetime disposable income

Lifetime labor earnings

	Age 45	Age 55	Age 65	Age 75
Benchmark	0.303	0.328	0.326	0.318
No frailty heterogeneity	0.268	0.277	0.283	0.272
$\Delta \downarrow$	11.5%	15.6 %	13.1%	14.5%

[▶ Details](#)

[▶ Go back](#)

Consumption inequality: Variance of log

	Age 45	Age 55	Age 65	Age 75
Benchmark	0.374	0.478	0.533	0.487
No frailty heterogeneity	0.305	0.371	0.383	0.374
$\Delta \downarrow$	18.5%	22.4 %	28.1%	23.2%

Aggregate effects of frailty heterogeneity

	NFH in model	NFH in SSDI	NFH in Disutility	NFH in Labor prod.	NFH in Med. Exp.	NFH in Mortality
	% change relative to benchmark					
GDP	2.14	2.39	0.59	1.75	0.13	-0.72
Consumption	0.91	1.33	0.46	1.14	0.09	-1.54
Capital	2.14	2.39	0.59	1.75	0.13	-0.72
Labor input	2.14	2.39	0.59	1.75	0.13	-0.72
Hours	3.44	2.76	0.79	2.22	0.17	-0.49
GDP per Hour	-1.26	-0.37	-0.20	-0.46	-0.04	-0.23

Note: NFH: no frailty heterogeneity.

- Removing frailty heterogeneity increases GDP per capita.
- Effects of higher LFP larger than effect of lower mortality.

Alternative Inequality Measure

Inequality in lifetime disposable income by age: Variance of Log

	Age 45	Age 55	Age 65	Age 75
Benchmark	0.303	0.328	0.326	0.318
No frailty heterogeneity	0.268	0.277	0.283	0.272
$\Delta \downarrow$	11.5%	15.6 %	13.1%	14.5%
No frailty shock	0.262	0.277	0.286	0.276
$\Delta \downarrow$	13.4%	15.6%	12.3%	13.3%
No frailty fixed effect	0.265	0.288	0.286	0.275
$\Delta \downarrow$	12.3%	12.4%	12.1%	13.7%

- Both shocks and fixed effect have a large effect on disposable income inequality.

Frailty and SRHS over the Life Cycle

Data: Household heads and spouses in 2003–2015 PSID

- Area shows share reporting each SRHS at each age.
- We partition frailty distribution at each age.
- Choose cutoffs to match dist. of SRHS at 25-29.
- Hold cutoffs fixed.

Health declines faster after age 50 when measured by frailty.

Why use frailty index?

Lots of action in the tails: need for finer grid.

Summary Statistics for PSID Sample

	2002	2004	2006	2008	2010	2012	2014	2016	Pooled 2002-2016
<i>Panel A: Mean (median) [standard deviation] of sample characteristics</i>

Average # of Years Observed (T)									5.78

Note: The summary statistics are for ages 25 to 64 of household heads and spouses. Individuals included in the sample are in at least 2 consecutive waves in PSID. Annual earnings is an individual's labor earnings for the year (in 2012\$). Annual hours is the sum of reported working hours for the year. Hourly wage is annual earnings divided by annual hours for labor force participants. Means are reported; median values are reported in parentheses; standard deviations are reported in brackets.

Blundell-Bond System GMM Estimation

- In short panels, fixed effect estimator biases can be severe (Nickell (1981 ECTA)).
- Following Blundell-Bond (1998, JoEtrics), we estimate the following using GMM

$$\begin{bmatrix} y_{i,t} \\ \Delta y_{i,t} \end{bmatrix} = \gamma \begin{bmatrix} f_{i,t} \\ \Delta f_{i,t} \end{bmatrix} + \alpha_1 \begin{bmatrix} y_{i,t-1} \\ \Delta y_{i,t-1} \end{bmatrix} + \alpha_2 \begin{bmatrix} y_{i,t-2} \\ \Delta y_{i,t-2} \end{bmatrix} + \delta \begin{bmatrix} \mathbf{Z}_{i,t} \\ \Delta \mathbf{Z}_{i,t} \end{bmatrix} + \begin{bmatrix} \varepsilon_{i,t} \\ \Delta \varepsilon_{i,t} \end{bmatrix}$$

- Full sample:
 - Use $f_{i,t-k}$, $y_{i,t-k}$, $k = 4, 5$ as instruments for differences
 - Use $\Delta f_{i,t-k}$, $\Delta y_{i,t-k}$, $k = 4, 5$ as instruments for levels
- Workers $k = 5, 6$ and frailty (reverse causality) $k = 6, 7, 8$.
- Use system estimator because earnings and frailty are close to random walk.

Blundell-Bond System GMM Estimation

- For our instruments to be valid it must be that:
 - lagged levels are uncorrelated with current error term.
 - correlation between endogenous variables and the unobserved (fixed) effect is constant over time.
- To check these assumptions we run the following tests:
 - AR(1) test for no ser corr in error terms (of diff eqn): this should be rejected (by construction)
 - AR(2) test for no second-order ser corr in error terms (of diff eqn): this should not be rejected
 - Hansen test for validity of level instruments: this should not be rejected
 - Diff-in-Hansen test for validity of diff instruments: this should not be rejected
- Also do additional robustness checks.

Dynamic Panel Additional Robustness Checks

- **Perform Diff-in-Hansen test on y-lag set only.**
- Check that estimates lie in expected range based on OLS and FE.
- Run F-tests of instrument power.
- Conduct robustness tests to instrument set.

Problem of Young Nonemployed Individual at $R - 1$

- Nonemployed individual with $j = R - 1$ solves

$$V^N(x, n_a) = \max_{c, a' \geq 0} u(c) + \beta p(j, f) E \left[\max \left\{ V^E(x', 1), V^R(x') \right\} \right]$$

subject to

$$\frac{a'}{1+r} + c + m^N(j, f, s) = a + Tr(x, n_a)$$

▶ Go back

Problem of a DI Beneficiary at $R - 1$

- DI beneficiary with $j = R - 1$ solves

$$V^D(x, n_d) = \max_{c, a' \geq 0} u(c) + \beta p(j, f, s) E[V^R(x')]$$

subject to

$$\frac{a'}{1+r} + c + m^D(j, f, s, n_d) = a + SS(\bar{e}) + Tr(x, n_d).$$

- n_d : number of periods on DI.

▶ Go back

Problem of a Retiree

- Retiree solves

$$V^R(x) = \max_{c, a' \geq 0} u(c) + \beta p(j, f) E[V^R(x')]$$

subject to

$$\frac{a'}{1+r} + c + m^R(j, f, s) = a + SS(\bar{e}) + Tr(x)$$

▶ Go Back

Equilibrium

- Return on assets, r , is exogenously given (small open economy)
- There is an aggregate production function

$$Y = AK^\alpha L^{1-\alpha}$$

where L is aggregate labor input = sum of hours \times productivity

- Wage per efficient unit of labor = marginal product
- Consolidated government budget holds – with exog. purchases g
- All measures are stationary – usual definition

Parametrization: Tax and Transfers

- Taxes includes
 - Proportional capital tax τ_K paid by firm
 - Federal income tax – HSV tax function
 - SS retirement & disability payroll tax – statutory tax formula
 - Medicare payroll tax

$$T(e) = e - \lambda e^{1-\tau} + \tau_{SS} \min\{e, 2.47\bar{e}_a\} + \tau_{med}e$$

- Transfers include
 - SS retirement & disability benefit – statutory benefit formula
 - SSI benefits to guarantee minimum DI payment \underline{b}
 - Welfare programs to guarantee minimum consumption floor \underline{c}

Estimation of Frailty Process: Deterministic Component

$$\text{Prob}(f_{ij} = 0) = \Phi(\text{quad}(\text{age}) + \nu_{ij})$$

$$\ln f_{ij} = \text{quartic}(\text{age}) + R_{ij},$$

$$R_{ij} = \alpha_i + z_{ij} + u_{ij},$$

$$z_{ij} = \rho z_{ij-1} + \varepsilon_{ij},$$

- Run OLS to remove time/sample duration effects
- Estimate zero frailty probit
- Estimate deterministic component of log frailty via SMM
- Calculate cohort-adjusted vars/covars of $R_{i,j}$
- Estimate process for $R_{i,j}$ using SMM
- Separate estimation for each educ group

Estimation of Frailty Process: Deterministic Component

	HS Dropout	HS Graduates	Col Graduates
age	1.26 (0.095)	0.988 (0.030)	0.999 (0.064)
age ²	2.19 (0.492)	1.40 (0.146)	2.04 (0.305)

Parametrization: Survival and OOP Med. Expenditure

- For survival: estimate (probit)

$$s_{ij} = \text{quad. poly. on age} + \text{quad. poly. on frailty} + \text{edu} + \text{gender}$$

Dataset: HRS

- For out of pocket medical expenditures: estimate

$$\text{oop}_{ij} = \text{cubic poly. on age} + \text{cubic poly. on frailty}$$

separate for each edu. & labor market status.

Dataset: MEPS

- Education: HSD, HSG, CG
- Labor market status: employed, non-employed and on Medicare, non-employed and not on Medicare

Estimating Productivity Profiles

Step 1: exclusion restriction

- Following Low & Pistaferri (2014) assume “potential” government transfers have different work disincentives for people w/ different health levels.
 - These effects are captured by interactions
- We regress participation on
 - log wage (1 and 2 lags), lag of frailty interacted educ., poly. on age, year dummies
 - interaction term: $\text{state} \times \# \text{ of kids} \times \text{marital status} \times \text{frailty}$
 - fixed effect
- We use estimated fixed effects in step 2

Estimating Productivity Profiles

Step 2: bias correction

- Follow: Al-Saddoon, Jimenez-Martin, & Labeaga (2019)
- Run log wage on
 - 2 lags of log wage
 - edu. interacted w/quad. of lag of frailty (treated exogenous – given our earlier findings)
 - age poly. + year dummies
 - fixed effects estimated in step 1

Hansen test (<i>p</i> -value)	0.107	0.096	0.107	0.096
Diff-in-Hansen test (<i>p</i> -value)	0.307	0.417	0.307	0.417

Estimating Productivity Profiles

Steps 3 and 4: estimating shock process

- Using results in step 2, remove effect of frailty
- Run the remainder (separate for college and non-college) on
 - quadratic in age
 - year dummies
- Estimate age profile for 25-49 using PSID and 50+ using HRS
- Back out residuals
- Estimate a RIP process for residuals using GMM and PSID

Estimating Productivity Profiles

Step 3: Deterministic component estimates

	Ages 25-49		Ages 50+	
	Non-college	Col Graduates	Non-college	Col Graduates
age	0.050 (0.003)	0.092 (0.005)	0.080 (0.018)	0.006 (0.029)
age ²	-0.0005 (0.0004)	-0.0009 (5.2e-6)	-0.0008 (0.0001)	-0.0002 (0.0002)
constant	1.878 (0.075)	1.196 (0.108)	1.224 (0.574)	3.932 (0.924)

Estimating Productivity Profiles

Step 4: Shock process estimates

	Non-college	Col Graduates
var. of transitory shock	0.0824 (0.0115)	0.0985 (0.0122)
var. of permanent shock	0.0165 (0.0049)	0.0181 (0.0059)
var. of fixed effect	0.0920 (0.0145)	0.1254 (0.0234)
persistence	0.9218 (0.0231)	0.9730 (0.0114)

Comparison with Low & Pistaferri (2014)

- Low & Pistaferri (2014) estimate the effect of disability on wages
- They have three disability groups $d = 0, 1, 2$
 - $d = 0$: those with no work limitation
 - $d = 2$: those with severe work limitation
 - $d = 1$: the rest
- We calculate mean frailty for each of these categories in our sample
 - $d = 0$ has mean frailty of 0.07
 - $d = 1$ has mean frailty of 0.18
 - $d = 2$ has mean frailty of 0.28
- Using these values and our estimated coefficients, we can compute effects that are comparable to Low & Pistaferri (2014)

Comparison with Low & Pistaferri (2014)

Table: Effect of work limitation on wages (% decline in wages relative to no limitation)

	mean frailty	Low & Pistaferri (2014) non-college	Our estimation			
			non-college	HSD	HSG	College
No limitation	0.07					
Moderate limitation	0.18	-5.7	-9.0	-13.1	-8.1	-5.8
Severe limitation	0.28	-17.7	-18.0	-26.1	-16.1	-13.9

- Note Low and Pistaferri's estimates are based on non-college sample only.

Frailty: Model vs Data

- Frailty process in model generates mean frailty levels by age and percentile groups that align closely with those in the data.

Assessment: DI and LFP by Education Groups

DI reciprocity rate (%), ages 25–64			
	HS Dropout	HS Graduates	Col Graduates
Data	11.8	6.6	2.7
Model	12.3	7.4	2.6

LFPR (%), ages 25–64			
	HS Dropout	HS Graduates	Col Graduates
Data	78	87	94
Model	76	86	94

- The model matches levels and patterns of DI reciprocity and LFP by education.

Calibration: What is Chosen to Match Targets

- Prob. of DI acceptance parameters: $\theta(f, n_a) = \min\{1, \kappa_0 f^{\kappa_1} n_a^{\kappa_2}\}$
 - Targets:
 - SSDI enrollment by frailty percentiles and 5-year age group (ages 25–64)
 - Rate of decline in DI acceptance by year since initial application (French and Song, 2014)
- Disutility of work parameters: $v(f) = \phi_0 + \phi_1 f^{\phi_2}$
 - Targets: LFP by frailty percentiles for age group 25 to 74.
- Discount factor β
 - Target: wealth to output ratio of 3.2.
- Average tax parameter λ
 - Target: federal income tax as % of GDP = 8%.

Calibration: Parameters Chosen using the Model

Table: Additional Parameters and Targets: Values

Parameter	Description	Value
β	discount factor	0.982
λ	HSV tax parameter	0.119

Moment	Target	Model
Wealth-output ratio	3.2	3.2
Federal Inc. Tax (% of GDP)	8.0	8.0

Sample Details

- Use PSID 2003–2017 (years 2002–2016)
 - Cannot construct frailty index in earlier waves.
- Sample consists of household heads and spouses aged 25–64 with non-missing labor earnings.
- Workers are defined as follows:
 - $LF_t = 1$ if hours ≥ 260 AND wages $> \$3/\text{hour}$
 - Worker = 1 if $LF_t = 1$ for all time periods observed
 - Wages = Annual labor earnings/Annual hours worked
 - Annual hours worked = (52 – weeks unemployed) \times average weekly hours
- Good/Bad health: frailty below/above 75th percentile
