

Sanctions and Misallocation. How Sanctioned Firms Won and Russia Lost.

NBER SI

Dzhamilya Nigmatulina

HEC Lausanne and LSE

July 26, 2023

Motivation

"Comprehensive economic sanctions have an indiscriminate impact on a country and can entail severe negative humanitarian consequences for the civilian population and third countries." (State Secretariat for Economic Affairs SECO, Switzerland)

- ▶ "Smart sanctions" - hurt the elites and not the average citizen.
- ▶ The US has over 70 countries under such sanctions today ([Felbermayr et al. 2020](#)).
- ▶ But: little evidence on how targets respond and on collateral damage on the rest of the economy.
- ▶ Evidence on targeted sanctions - sanctions against specific strategic firms in 2014-2020 in Russia. Data on 600,000 Russian firm balance sheets.

Motivation

- ▶ Sanctions target strategic, "important" firms \Rightarrow the impact of sanctions on the rest of the country is ex-ante non-trivial:

- ▶ Government may respond endogenously to protect targeted firms, reallocating resources towards targets
- ▶ The sanctions episode 2014-2020 in Russia - an ideal setting

This Paper

- ▶ How sanctions affect the sanctioned firms and the overall economy?
- ▶ **D-i-D** The role of sanctions+government response on firms.
 - ▶ A natural experiment of US sanctions, rolled out in 2014 - 2020
- ▶ **Misallocation framework** Use a framework to get 1) sufficient statistic for being "over-" or "under-resourced" for each firm
- ▶ **D-i-D + Framework** Feed back the estimates from the D-i-D into three different frameworks to estimate the aggregate effect of sanctions on country's TFP: (use Hsieh and Klenow (2009), Levinsohn and Petrin (2012), and Baquae and Farhi (2020))

Findings

- ▶ US sanctions targeted over-resourced firms.
- ▶ Sanctioned firms saw a **boost** in capital, revenue, and assets after sanctions, linked to increased subsidies, contracts, and short-term loans.
- ▶ Instead of correcting resource misallocation, sanctions **worsened allocation** (due to government protection measures).
- ▶ The combination of sanctions and government intervention led to a GDP reduction of up to 1%.

Examples: Stroigazmontazh and Promsvyazbank

- ▶ Case 1:
 - ▶ 2014: Arakdy Rotenberg is sanctioned
 - ▶ 2015: Stroigazmontazh (owned by Rotenberg) wins the government contract of 223,1 bln roubles to build the bridge to Crimea.
- ▶ Case 2:
 - ▶ Promsvyazbank re-purposed to compensate the losses from sanctions of Russia's defence sector.

Contributions to the Literature

- ▶ **The effects of economic sanctions** (Ahn & Ludema 2020, Tuzova & Qayum 2016, Crozet & Hinz 2016, Haidar 2017, Draca et al. 2019, Stone 2016, Gold et al. 2019, Mamonov and Pestova 2022).
 - ▶ Quantify the effect of sanctions on the economy through aggregate TFP
- ▶ **Effects of political connections for firm-level outcomes** (Hsieh & Song 2015, Berkowitz et al. 2017, Brandt et al. 2018, Bussolo et al. 2019, Brown et al. 2006).
 - ▶ Highlight a novel mechanism of how politically connected firms are (over-) protected from a negative shock
- ▶ **Allocative efficiency for aggregate outcomes** (Hsieh & Klenow 2009, Restuccia & Rogerson 2008, Baqaee & Farhi 2020, Busso et al. 2013)
 - ▶ One of the first papers to combine causal inference and a misallocation framework (along with Rotemberg 2019, Bau & Matray 2020)

Roadmap

1. **Modelling misallocation** to quantify pre-existing distortions
2. **Data** : 600k firms and sanctions
3. **D-i-D**: Quasi-experiment of sanctions
4. **Frameworks + D-i-D**: Aggregate effects of sanctions on TFP
5. Counterfactual exercises: how large are the aggregate effects relative to baseline misallocation?

Misallocation Framework

- ▶ An efficient, or distortion-free, allocation would be one in which the marginal value product of inputs is equalised across production units.
- ▶ **Stylized example:**
 - ▶ An industry with two firms: Rosneft (SOE, politically connected), and a private firm, Lukoil
 - ▶ Rosneft's marginal value product of capital is \$5 and Lukoil's is \$10.
 - ▶ Taking one unit of capital from Rosneft to Lukoil will increase the output in the industry by \$5.
 - ▶ Reallocate up until the marginal value product of capital is the same between Rosneft and Lukoil to attain the highest output in the industry using existing inputs.

Misallocation Framework

- ▶ I model misallocation as implicit taxes (or "wedges") on the prices of inputs

$$\pi_i = p_i F_i(K_i, L_i) - (1 + \tau_i^L)wL_i - (1 + \tau_i^K)rK_i \quad (1)$$

- ▶ The profit-maximizing firm will equalize the marginal revenue product to the marginal cost of input.

$$\{K_i\} : p_i \frac{\partial F_i(K_i, L_i)}{\partial K_i} = (1 + \tau_i^K)r \equiv MRPK_i \quad (2)$$

$$\{L_i\} : p_i \frac{\partial F_i(K_i, L_i)}{\partial L_i} = (1 + \tau_i^L)w \equiv MRPL_i \quad (3)$$

- ▶ Key idea: in the absence of wedges (τ_i^L and τ_i^K), MRPK and MRPL should equalize, since if not, the inputs would flow to the firms that would generate more value added on the margin.

Assumption to calculate MRPK and MRPL

Cobb-Douglas firm production function

- ▶ allows to use share of capital and labor in revenue to back out MRPK and MRPL directly in the data

$$\{K_i\} : \alpha_s \frac{p_i F_i(K_i, L_i)}{K_i} = (1 + \tau_i^K) r \equiv MRPK_i \quad (4)$$

$$\{L_i\} : (1 - \alpha_s) \frac{p_i F_i(K_i, L_i)}{L_i} = (1 + \tau_i^L) w \equiv MRPL_i \quad (5)$$

Firm data

- ▶ ~600k firms from Spark Database
- ▶ balance-sheet, tax, employment, ownership information and government contracts at the firm-by-year level.
- ▶ private and state-owned firms covering manufacturing, agriculture and services sectors.
- ▶ years 2012-2020
- ▶ representative panel of medium and large firms
- ▶ these firms' value added covers 61% of Russian value added (and revenues more than 1.5 times of the Russian GDP)

Coverage of the Russian economy

Sanctioned vs non-sanctioned

- ▶ The US imposed two types of sanctions in years 2014-2020 in a staggered fashion
 - ▶ **Input sanctions** or "SSI" (ban on long-term loans and other imported inputs), against firms
 - ▶ **Blocking sanctions** or "SDN" (ban on any transaction, e.g. export, import, lending, issuing stock, leasing), against individuals and firms

- ▶ **How were targets chosen?** "oligarchs who profit from [Russia's] corrupt system", those operating in Russia's arms or related materiel sector; entities owned or controlled by a senior Russian government official, entities and individuals operating in specified sectors of the Russian economy (Congressional Research Service, 2020)

Sanctions Data

- ▶ The SSI and SDN sanctions extend on any firm owned by a sanctioned individual or firm by more than 50 per cent ("OFAC rule of 50")
- ▶ A firm is sanctioned if
 - ▶ the firm is listed by the US Department of Treasury
 - ▶ the firm is a historical majority-owned subsidiary of the above
 - ▶ if the firm is owned by or a subsidiary of the firm owned by an SDN individual (using First, Middle and Last name match) with confirmed ownership at the time of imposition of sanctions
- ▶ I study both types of sanctions, input sanctions and blocking sanctions, together and separately.

Sanctions by type and ownership

Sanction type	Number	Ownership
		Share state-owned
SDN	277	19%
SSI	397	12%
SSI and SDN	458	17%
Total	1,132	16%

Table: 1. Sanctions by ownership

In the overall firm sample, only 4% of all firms are SOEs.

Existing distortions. Sanctioned vs non-sanctioned firms

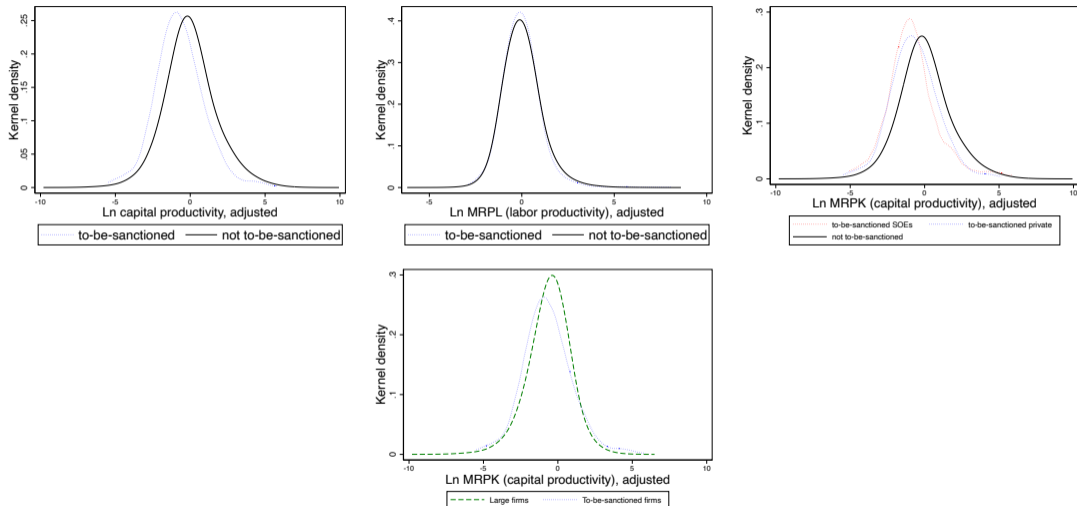

Figure: Firms before 2015 (time-invariant component, de-meaned by 4-digit industry)

Estimating Equation

$$Y_{ijt} = \phi_i + \gamma_{jt} + \theta_{st} + \beta_1 \text{Sanction}_{it} + u_{ijt} \quad (6)$$

- ▶ Y_{it} is $\ln(MRPK_{ijt})$, $\ln(K_{ijt})$, $\ln(ValueAdded_{ijt})$, $\ln(Revenue_{ijt})$ and other firm-level variables.
- ▶ Sanctions_{it} is the time-variant sanctions dummy at firm-level
- ▶ ϕ_i is firm FE
- ▶ γ_{jt} is a 4-digit industry-year FE
- ▶ θ_{st} size-by-year fixed effects

- ▶ Cluster the errors two-way: by firm and 4-digit-industry-by-year.

Robustness Checks

- ▶ Main results, gradually adding FE result
- ▶ Firm exit result
- ▶ Spillovers result
- ▶ SSI versus SDN sanctions result
- ▶ Heterogeneity of effects result
- ▶ Heterogeneity of effects by strategic status result
- ▶ Effect on A_i (or $TFPQ_i$) result
- ▶ Raw mean changes, treatment and control result

Aggregate effects?

- ▶ Use three frameworks to aggregate the effects from the D-i-d and be able to compare to other papers:
 - ▶ Hsieh and Klenow model as baseline (shortcut and full model)
 - ▶ Levinsohn and Petrin (2012), as reformulated by Baquae and Farhi (2019)
 - ▶ Full Baquae and Farhi (2020)

- ▶ I calibrate the frameworks to the Russian economy (and Russian distortions, corrected for measurement error)
- ▶ I plug the estimates from the regressions on inputs and change in MRPK (proxy for wedges) to get ΔTFP .
- ▶ **Why not get ΔGDP ?** Empirically, it is impossible to causally separate the aggregate K changing in Russia due to sanctions (from the oil price shock, currency devaluation, other Macro effects)

Hsieh and Klenow: Intuitive Shortcut

Shortcut (for intuition): if A_i and $TFPR_i$ are jointly lognormally distributed (and the physical productivity (A_i) of the firms stays the same):

$$\Delta \log TFP_s = -\frac{\sigma}{2} * VAR(\log TFPR_i + \alpha \Delta \log MRPK_i) \quad (7)$$

- ▶ $\Delta \log MRPK_i$ is taken from **Table 9, column 1**.
- ▶ $\log TFPR_i \equiv \log\left(\frac{p_i F_s(K_i, L_i)}{K_i^{\alpha_s} L_i^{1-\alpha_s}}\right) \propto \log(MRPK_i^{\alpha_s} * MRPL_i^{1-\alpha_s})$ is obtained by regressing $\log TFPR_{it}$ on year and firm fixed effects using the pre-period sample.
- ▶ ΔTFP is a geometric average of TFP_s using sectoral shares of value added in total GDP (θ_s) as weights.

Full model

Hsieh and Klenow: Intuitive Shortcut

Shortcut (for intuition): if A_i and $TFPR_i$ are jointly lognormally distributed (and the physical productivity (A_i) of the firms stays the same):

$$\Delta \log TFP_s = -\frac{\sigma}{2} * VAR(\log TFPR_i + \alpha \Delta \log MRPK_i) \quad (7)$$

- ▶ $\Delta \log MRPK_i$ is taken from **Table 9, column 1**.
- ▶ $\log TFPR_i \equiv \log\left(\frac{p_i F_s(K_i, L_i)}{K_i^{\alpha_s} L_i^{1-\alpha_s}}\right) \propto \log(MRPK_i^{\alpha_s} * MRPL_i^{1-\alpha_s})$ is obtained by regressing $\log TFPR_{it}$ on year and firm fixed effects using the pre-period sample.
- ▶ ΔTFP is a geometric average of TFP_s using sectoral shares of value added in total GDP (θ_s) as weights.

Aggregate results

Framework	ΔTFP
Hsieh and Klenow, jointly log-normal assumption	-0.33%
Hsieh and Klenow, full model	-0.10%
Levinsohn and Petrin (2012)	-1.02%
Baqaee and Farhi (2020)	-0.10%

Table: Change in aggregate TFP due to the joint effect of sanctions and government support

Levinsohn and Petrin

Baqaee and Farhi

How does the $\Delta \log TFP_s$ compare to the existing TFP gaps?

How I quantify TFP gaps

- ▶ Measure overall TFP gap: 51.1 percentage points
- ▶ Measure the TFP gap between the sanctioned and non-sanctioned firms: 30.5% of the overall TFP gap Counterfactual result

Conclusion

- ▶ Sanctions, combined with shielding have led the targeted firms to gain 32% more capital and 20% more revenue relative to a non-sanctioned firm.
- ▶ Allocation of resources worsened.
- ▶ Subsidies and contracts were likely allocated at the expense of everyone else.

Result:

- ▶ **Did sanctions bring collateral damage?** Nothing but collateral damage (but, it was self inflicted)
- ▶ Were sanctions "effective"? No: elites became empowered, rather than "split"

VoxEU summary

Paper & updates

Full model of the economy

▶ **Level 1**

$$Y_{si} = A_{si} K_{si}^{\alpha_s} L_{si}^{1-\alpha_s} \quad (8)$$

▶ **Level 2**

$$Y_s = \sum_i \left(Y_{si}^{\frac{\sigma-1}{\sigma}} \right)^{\frac{\sigma}{\sigma-1}} \quad (9)$$

▶ **Level 3**

$$Y = \prod_{s=1}^S Y_s^{\theta_s} \quad (10)$$

where $\sum_i \theta_s = 1$

◀ back

TFP from the model structure

- ▶ Country TFP is the Cobb-Douglas average of the Solow residual in each sector after accounting for total inputs used in each sector.

$$Y = \prod_{s=1}^S (TFP_s K_s^{\alpha_s} L_s^{1-\alpha_s})^{\theta_s} \quad (11)$$

◀ back

Counterfactuals: Measuring the contribution of wedges between groups of firms to misallocation

- ▶ **Counterfactual 1** Equalize MRPK and MRPL within each four-digit industry, keeping total industry capital and labour fixed, calculate the TFP in each industry. [formula](#)

- ▶ **Counterfactual 2** I equalize MRPL and MRPK only within ownership-by-industry groups [formula](#)

- ▶ Compare the resulting aggregate TFP's.

Counterfactual Results: TFP gap due to SOEs

TFP*: Equalize all wedges within industries

TFP_c: Equalize wedges within status-industry groups

Measures	Count	TFP/TFP*	TFP _c /TFP*	Gap due to between-group wedge
To-be-sanctioned versus not	57,279	49.9%	84.7%	30.5%

Table: Counterfactual exercises

- ▶ The sanctioned vs non-sanctions wedge explains $[(100-84.7)/(100-49.9)=30.5\%]$ of the distance to the frontier.
- ▶ Sanctions explain about 1% of the "sanctioned group"-driven distance to the frontier

TFPR formula

Assuming Cobb-Douglas production function (with the same exponents within an industry s), I also define a summary measure of the wedges with respect to both inputs:

$$TFPR_i \equiv \frac{p_i F_s(K_i, L_i)}{K_i^{\alpha_s} L_i^{1-\alpha_s}} \propto MRPK_i^{\alpha_s} * MRPL_i^{1-\alpha_s} \quad (12)$$

◀ back

Wedges between SOEs and private firms

- ▶ One can derive group wedges by equalizing all wedges within a group and only keeping the wedges across groups.
- ▶ This is equivalent to redistributing group capital and labor efficiently within the group

$$TFPR_{priv} = \frac{\left(\sum \left(\frac{A_i}{\kappa} \right)^{\frac{1-\eta}{\eta}} \right)^{\eta}}{(K_{priv})^{\alpha\eta} (L_{priv})^{(1-\alpha)\eta}} \quad (13)$$

Where $\eta = 1/\sigma$

[◀ back](#)

Framework

- ▶ Model a-la Hsieh and Klenow: misallocation across firms within industry

$$\pi_i = P_i Q_i - (1 + \tau_i^L) w L_i - (1 + \tau_i^K) r K_i \quad (14)$$

$$\max_{L_i, K_i} \pi_i = P Q^{\frac{1}{\sigma}} (A_i K_i^\alpha L_i^{1-\alpha})^{\frac{\sigma-1}{\sigma}} - (1 + \tau_i^L) w L_i - (1 + \tau_i^K) r K_i$$

$$\{L_i\} : (1 - \alpha) \left(\frac{\sigma - 1}{\sigma} \right) \frac{P_i Q_i}{L_i} = (1 + \tau_i^L) w \equiv MRPL_i \quad (15)$$

$$\{K_i\} : \alpha \left(\frac{\sigma - 1}{\sigma} \right) \frac{P_i Q_i}{K_i} = (1 + \tau_i^K) r \equiv MRPK_i \quad (16)$$

Framework

- ▶ One can define a summary statistic of both labor and capital wedges, name it "TFPR"

$$TFPR_i \equiv \frac{P_i Q_i}{K_i^\alpha L_i^{1-\alpha}} \propto MRPK_i^\alpha * MRPL_i^{1-\alpha} \quad (17)$$

- ▶ Knowing the elasticity of substitution, one can get an expression for the firm TFP (or productivity) object, the "TFPQ":

$$TFPQ_i \equiv TFP_i \equiv A_i \propto \frac{(P_i Q_i)^{\frac{\sigma}{\sigma-1}}}{K_i^\alpha L_i^{1-\alpha}} \quad (18)$$

Where $\eta = 1/\sigma$ [◀ back](#)

Framework

@hookitemize

The overall industry productivity depends on the variance of MRPK and MRPL (or the variance of the TFPR).

The lower is the variance, the higher is the aggregate industry TFP

$$TFP_s = \left(\sum_i \left(A_i \left(\frac{\overline{MRPL}}{MRPL_i} \right)^{1-\alpha} \left(\frac{\overline{MRPK}}{MRPK_i} \right)^\alpha \right)^{\sigma-1} \right)^{\frac{1}{\sigma-1}} \quad (19)$$

$$TFPe_s = \left(\sum_i (A_i^{\sigma-1}) \right)^{\frac{1}{\sigma-1}} \quad (20)$$

In which sectors SOEs are more productive

Out of 80 sectors, TFPR is higher for SOEs in the following sectors only:

- ▶ Manufacture of textiles
- ▶ Provision of services in the field of elimination of the consequences of pollution
- ▶ Film, video and television program production, sound recording and sheet music
- ▶ Activities auxiliary to financial services and insurance

back

How I calculate the change in practice.

- ▶ Create sanctioned and non-sanctioned groups within each industry, equalizing wedges between firms in the group.
- ▶ Allocate capital to the sanctioned group, reducing its MRPK by 10% (Table 9).
- ▶ Assign remaining capital to the non-sanctioned group.
- ▶ Re-calculate new aggregate TFP for each industry and overall, comparing it to the TFP with initial wedge between sanctioned and non-sanctioned firms.
- ▶ Observed decline in TFP is approximately -0.1%.

[back](#)

Baqaee and Farhi (2019) and Levisohn and Petrin (2012)

Like Bau and Matray (2023), I adapt their version of the expression to aggregate the changes of capital inputs between distorted producers. (I assume that the change in A_i is 0)

$$\Delta \log(TFP_s) \approx \sum_{i \in s} \lambda_i \alpha_i^K \frac{\tau_i^K}{1 + \tau_i^K} \Delta \log K_i \quad (22)$$

where $i \in s$ is a set of firms and s is the set of industries. [◀ back](#)

$$\frac{d \log TFP}{d \log \mu_k} = -\tilde{\lambda}_k - \sum_f \tilde{\Lambda}_f \frac{d \log \Lambda_f}{d \log \mu_k} \quad (23)$$

where

- ▶ k is a firm
- ▶ $\tilde{\lambda}_k$ is the "cost-based Domar weight", a share of firm k in the economy's costs.
- ▶ $\tilde{\lambda}_k$ is defined by $\tilde{\lambda}_k \equiv b' \tilde{\Psi} \equiv b'(I - \tilde{\Omega})^{-1}$, where $\tilde{\Omega}$ is a cost-based input-output matrix, whose cell in row i and column j ($\tilde{\Omega}_{ij}$) is the share of firm's j 's sales in firm i 's costs.
- ▶ $\tilde{\Lambda}_f$ is the "cost-based Domar weight" of the factor j , which in my case is capital or labor.
- ▶ Λ_f is the Domar weight of factor f , or the sales share of the factor in GDP.
