How to Grow an Invoicing Currency: Micro Evidence from Argentina^{*}

May 2025

Abstract

How can a currency achieve more widespread international use? We study the internationalization of the Chinese renminbi (RMB) through the lens of a unique policy experiment in Argentina. In 2023, amid a severe dollar shortage, Argentina expanded a currency swap line with the People's Bank of China. Within the next few months, the share of imports from China invoiced in RMB surged rapidly to nearly 50% – displacing the US dollar, which had previously accounted for virtually all invoicing. Following the presidential election of late 2023, as macroeconomic policies changed and the dollar shortage eased, invoicing in RMB declined. We explore the mechanisms behind this aggregate pattern, using rich firm-level data on imports, bank-firm loan relationships, and bank balance sheets. Our results indicate that banks played a key role, in line with the dollar shortage narrative. First, firms with pre-existing relationships to banks with limited US dollar loans were more likely to switch to RMB. Second, firms borrowing from a Chinese state-owned bank were significantly more likely to use RMB. We also document firm-level spillovers, with RMB use for imports from China increasing the likelihood of RMB use for imports from other countries. Finally, we observe an effect on trade volumes. Firms switching to RMB saw increased total imports.

1 Introduction

Will the Chinese renminbi (RMB) become a global currency and eventually challenge the US dollar's dominant currency status? What are the avenues through which this could happen? Eichengreen et al. (2024) argue that while the British pound and later the US dollar became global currencies after being traded in deep and liquid financial markets, the future expansion path for the RMB might be different. The beachhead for the internationalization of the RMB, they suggest, might be its use as an invoicing currency for trade with China. For this purpose, swap lines between central banks can provide easy access to the RMB, replacing deep financial markets as the traditional gateway to foreign currency. While this is an important and timely debate, there is a paucity of empirical evidence to ground it, especially regarding the mechanisms through which global currencies might emerge.

In this paper, we explore a unique policy experiment in Argentina that sheds light on this debate. In early 2023, amid a foreign currency shortage and dwindling international reserves, Argentina signed an agreement involving a large expansion of an RMB currency swap line extended by the People's Bank of China (PBOC). During the following months, the RMB rapidly gained ground as an invoicing currency in Argentina for a large share of imports from China. While previously nearly all imports from China were invoiced in dollars, the RMB share reached about 50% by mid-2023. Hundreds of Argentine companies had switched from US dollars to RMB as a payment currency for foreign imports. This included makers of electronics, auto parts and textiles as well as oil and mining firms.¹ RMB use also spread, to some extent, to imports from other countries. Later that year, after the presidential election of October/November 2023 that unexpectedly brought Javier Milei to power and ushered in economic policy changes, the de-dollarization trend reverted and the US dollar regained prominence as an invoicing currency, with RMB invoicing declining to less than 10% of imports from China. Our goal in this paper is to unveil the mechanisms behind this large and swift change in invoicing currencies.

Our work departs from the existing literature by analyzing invoicing currency choices in an emerging economy context where government policies play an important role, against the backdrop of a foreign currency shortage and a currency crisis. Until this point, the literature has made most progress in documenting the market-driven determinants of invoicing currency choices in stable economies. In the context of the dollar vs. RMB debate, our setting is relevant because it is precisely through loans to emerging economies in crisis situations that China's government could promote the internationalization of the RMB. In fact, many of China's swap lines have been signed

¹Many firms used RMB to pay for key production inputs sourced from abroad. According to June 2023 news report by Bloomberg, as the president of Whirlpool Latin America put it, "We've had to stop the factory at some points and that's not good for business, productivity nor quality. We're working to see how we can leverage this new avenue of flows to be able to continue importing materials."

with emerging economies facing currency crises and that are in need of external financing.²

To illustrate the mechanisms at work, we construct a rich and novel dataset of Argentine firms' international trade transactions, bank-to-firm loans, and bank balance sheets. The trade data consists of the universe of import and export transactions from January 2022 to June 2024. The data identify the Argentine firm involved, the product and value of the transaction, and the invoicing currency used. The second dataset, on bank-to-firm loans, is provided by the Argentine central bank and reports the outstanding loans of each firm with each bank at a monthly frequency over the same period. Finally, we use balance sheet data for each Argentine bank. As a key feature, they report total loans broken down by currency.

With these data, we explore the mechanisms driving invoicing currency choices. Our evidence indicates that banks played a key role. First, we find evidence of a foreign currency shortage mechanism, in line with the macroeconomic narrative. Firms having relationships (prior to the swap expansion) with banks with higher US dollar loan shares were less likely to switch to RMB invoicing later on. Further, we see that this effect was stronger in the very period in which the dollar shortage in Argentina was most critical. The dynamics of this effect match the aggregate dynamics of the severity of the dollar shortage in Argentina, which peaked in the last two quarters of 2023 and eased following the presidential election.

Second, we find that a Chinese state-owned bank with a large presence in Argentina (the Industrial and Commercial Bank of China, ICBC) played a separate and important role in spurring importing firms towards RMB adoption for invoicing. We find that firms which borrowed from ICBC prior to the swap expansion were substantially more likely to invoice in RMB after the swap line was expanded.³

Finally, we also find that large firms were more likely to adopt invoicing in RMB. The most straightforward interpretation is that operating in RMB entails a fixed cost that larger firms are more willing to pay.

Having documented invoicing patterns for imports from China, we then examine firms' RMB use for imports from the rest of the world. As a reference point, before the expansion of the swap agreement, the US dollar also dominated imports from the rest of the world, with the euro having a modest market share in imports from Europe. Our first finding is that after the swap expansion, with the same timing as seen for imports from China, there is a sudden increase in imports from other countries also invoiced in RMB, with a matching decline following the presidential election. This pattern can be observed across many products and import source countries.

At the firm level, we see that firms invoicing imports from China in RMB are also substantially

²In fact, countries with Chinese swap lines have had currency crisis episodes in 17% of the years since 1990 (Behavioral Finance & Financial Stability Project, 2025).

³ICBC was the sixth largest lender in Argentina before the swap expansion was implemented, and it has more than 100 branches spread throughout the country. While the swap agreement established ICBC as a clearinghouse, all banks in Argentina were eligible to provide RMB for imports, and indeed many of them immediately started offering that service.

more likely to invoice imports from the rest of the world in RMB. This finding suggests spillover effects in invoicing across countries. Also at the firm level, we find that firms which have relationships with ICBC and banks with lower US dollar loan shares are also more likely to switch to RMB invoicing for their imports from the rest of the world. Overall, this evidence implies that if China can promote RMB use for its own exports, to a certain extent spillovers might eventually spread RMB use to trade between other countries.

As a robustness check to corroborate our findings, we draw on equivalent transactions data for importers from neighboring Chile. Chile also has a swap line with China (signed in 2015) but did not experience a currency crisis during the period under study. We compare import transactions from China by Chilean importers to those by Argentine importers. We find it was only the Argentine importers who experienced a sharp increase in RMB invoicing for imports from China, followed by a swift decline. This result suggests that the temporary substitution of RMB for US dollars in trade invoicing by Argentina was brought about by the unique combination of the RMB swap line availability with the dollar shortage.

In the last part of the empirical analysis, we document that RMB use also had an impact on trade volumes. Firms invoicing in RMB following the swap agreement expansion saw a substantial increase in imports from China. The timing of this volume effect coincided with the spike of RMB use. It was also temporary, declining towards the end of 2023 and during 2024. We do not find evidence that increased imports from China reduced imports from the rest of the world. If anything, we also see an increase in imports from other countries. This implies that total imports increased during the period of increased RMB invoicing. Overall, these findings are consistent with the narrative that Argentine imports were restricted by the dollar shortage, which was eased in turn by access to RMB.

Contribution to the literature We contribute to various strands of the literature, in particular the literature on currency invoicing in international trade, the literature on banking and trade as well as the literature on currency swaps, central bank reserves, and foreign capital controls. We also speak to the emerging literature on geoeconomics that charts the political ambitions of major economic power players, in this case China.

Our work adds a new perspective to the literature on invoicing currencies in international trade (Goldberg and Tille, 2008, 2016; Gopinath et al., 2020; Amiti et al., 2022; Boz et al., 2022; Chen et al., 2022; Corsetti et al., 2022; Benguria and Wagner, 2024). This literature has produced several important insights that appear to be robust across several countries. These include the role of strategic complementarities, the link between invoicing currencies in exports and production costs, the widespread use of vehicle countries and the dominance of the dollar in world trade.

We make the following contributions to this literature. First, we provide new evidence on the emergence of the RMB as an invoicing currency and its rivalry with the US dollar. There is little

evidence on this topic because it is a new and developing phenomenon and to the best of our knowledge, we provide the first firm-level evidence in this regard. Second, we provide evidence on a mechanism that is novel to the literature: the role of banks in shaping the invoicing currency choices made by firms. We also show that this mechanism is important quantitatively.

Our findings emphasize new perspectives. First, while the literature has shed light on market mechanisms such as strategic complementarities and the cost channel, we complement this by showing that government policies and the macroeconomic environment can have an important impact on invoicing currency choice. Second, while the literature often assumes the importer is passive and the exporter sets the invoicing currency, our findings show that variation across importing firms explains a large share of invoicing currency patterns. Third, our findings challenge the view that invoicing currency use is essentially static over time. With few exceptions, evidence from various countries thus far available in the literature shows that aggregate invoicing currency shares tend to be very stable and persistent, with only small and gradual changes over time (Boz et al., 2022). Our findings stand in sharp contrast to this notion. We find that in the context of a currency crisis and with significant government intervention, invoicing currency use can shift substantially and extremely quickly.⁴ Fourth, we show how invoicing currency choice is linked across countries, given that firms which adopt RMB for imports from China are also more likely to adopt it when importing from other countries.

Regarding the global role of the RMB, Bahaj and Reis (2024) argue that swap lines created by the PBOC between 2009 and 2018 have been instrumental in increasing the international use of RMB as a payment currency. As an alternative mechanism, they model the currency of working capital and the currency of invoicing as complements, and they stress the role of central banks in lowering the volatility of borrowing costs in RMB through swap lines. They provide evidence for aggregate SWIFT data on cross-border payment settlements at monthly frequency. In the context of our micro data, we do not find any empirical evidence of complementarity between working capital and invoicing in the same currency. Through the lens of the model proposed by Bahaj and Reis (2024), a swap line expansion from China would lead to increased bank lending in RMB, which in turn would spur invoicing of Argentine trade in RMB. But when we compare Argentine bank balance sheet data in 2022Q4 (before the swap expansion) to 2023Q4 (after the swap expansion), we see no or at most a negligible increase in RMB lending.⁵ We therefore find no evidence

⁴Episodes whereby a country switched invoicing currencies as abruptly are relatively rare in the literature. For example, Crowley et al. (2024) find a swift decline in sterling invoicing for British exports in the years after the Brexit referendum. Boz et al. (2022) show that invoicing currency shares can also change under other circumstances, in particular for countries such as Croatia and Poland when joining the European Union and for countries in the euro area's immediate neighborhood such as Norway (see their Figure 10). Similarly, Benguria and Wagner (2024) show that Chilean exporters to euro zone countries start to adopt the euro after its introduction. But in all those cases, the switch towards euro invoicing is gradual and takes place over several years.

⁵The "other" currency category (which includes RMB) is tiny in 2022Q4 and remains tiny afterwards. This is true even for the balance sheet of ICBC. Gopinath and Stein (2021) also stress the importance of domestic loans and debt denominated in the dominant currency.

of the particular mechanism suggested by Bahaj and Reis (2024). We stress, however, that our analysis concentrating on Argentina is not designed to be a test of their mechanism. Such a test would ideally be based on equivalent data for many more countries.

Further empirical evidence on the effect of swap lines on RMB use comes from Georgiadis et al. (2021). In line with Bahaj and Reis (2024) but focusing on trade invoicing currencies rather than broader SWIFT payments, they find that countries with a PBOC swap line increase the RMB invoicing share of their trade compared to countries without a swap line. In addition, Eichengreen et al. (2024) provide useful context for our study. They map the internationalization of the RMB so far and discuss policies by China that might further expand its role. Beyond these papers, the evidence on the global role of the RMB is still limited as this is a relatively new development.

Our paper also belongs to a literature analyzing the link between banks and trade flows (Amiti and Weinstein, 2011; Paravisini et al., 2015; Niepmann and Schmidt-Eisenlohr, 2017; Correa et al., 2023; Federico et al., 2025). We build on the prevalent idea in this literature that banks that firms borrow from can shape the impact of external shocks. However, our work is the first to focus on the role of banks shaping invoicing currency choices. In addition, our findings emphasize the role of state-owned banks.

Our focus on the rivalry between the US dollar and the RMB also speaks to the flourishing literature on geoeconomics. From a theoretical perspective, Chahrour and Valchev (2024) develop a quantitative model to assess whether the dominant role of the US dollar could be challenged by the RMB in an environment of escalating geoeconomic conflict and rising protectionism. Eichengreen et al. (2019) study the currency of international reserves, finding that they are function of not only economic factors but also geopolitical concerns. In turn, Eichengreen (2024) discusses the prospects for the global dominance of the dollar under future scenarios of the US-China economic relationship.

Organization The rest of the paper is organized as follows. In Section 2 we motivate our empirical setting by providing institutional and historical context for the role of foreign currency use in Argentine international trade. In Section 3 we describe our dataset. Section 4 presents our empirical results. Section 5 concludes.

2 Motivation and background

We briefly describe trade relations between Argentina and China and the history of their bilateral currency swaps. We also provide some context for the macroeconomic and political background, in particular regarding Argentina's foreign currency shortage and China's efforts to internationalize the RMB.

2.1 Trade relations between Argentina and China

In 2023 China was Argentina's second largest trading partner after Brazil, followed by the US in third position, and Argentina ran its biggest bilateral trade deficit with China.⁶ Argentine imports from China mainly comprise manufacturing products such as machinery and equipment, office and computing machinery and chemical products. Panel A of Figure 1 shows the China share of Argentine imports. It rose rapidly from below 5% in the late 1990s to around 20% by 2015.

In the opposite direction, Argentine exports to China are concentrated in the primary sector, mainly consisting of agricultural products, mining, food products, beverages, and basic metals.⁷ Panel B of Figure 1 plots the China share of Argentine exports. It also rose since the 1990s but stabilized at just below 10% since the early 2000s.

2.2 The history of currency swaps between Argentina and China

The PBOC does not publish details on its currency swap arrangements with foreign partners. We therefore outline the history of Argentina-China currency swaps based on newspaper reports and selected references. In Appendix Section A.1 we provide a more detailed timeline with key dates on the history of China-Argentina currency swaps.

In 2009 China started setting up a global network of bilateral swap arrangements which eventually sprawled to dozens of partner countries. In the same year, China entered its first bilateral swap agreement with Argentina, worth USD \$11bn. Initiated after Argentina's 2008/09 economic crisis, the swap was supposed to strengthen Argentina's foreign currency reserves and act as a buffer against potential international illiquidity problems. But the swap remained dormant before expiring after three years without ever having been tapped into (Horn et al., 2023).

In July 2014 in the immediate aftermath of Argentina's sovereign debt default, a new swap agreement was signed totalling USD \$11bn. This time, it was fully used by October 2015, representing about 40% of Argentina's foreign currency reserves. In 2018, Argentina and China agreed to increase the swap line to USD \$19bn, and by December 2018 Argentina's total outstanding swap debt was close to that limit. By December 2021, the swap line was further increased to USD \$20.5bn, representing 51.6% of foreign currency reserves held by the Banco Central de la República Argentina (BCRA).⁸

Our period of study starts in January 2023 by which time the PBOC had increased the swap line by another USD \$5bn. Throughout the paper we will refer to the period from January 2023 as the time when the swap agreement was 'expanded,' or the 'expansion' period. In June 2023, the swap

⁶In 2023 Argentina received about 20% of its total imports from China, worth over USD \$14bn. Argentina exported over USD \$5bn to China, corresponding to about 8% of its total exports. By comparison, Argentine GDP (in current USD) was \$641bn.

⁷Bekerman et al. (2022) show that nearly 90% of Argentina's exports to China are commodities (agricultural and mining) as well as food and beverages, compared to 60% to the rest of the world.

⁸See Arnold (2023b) for details covering the period from 2014 to 2022.

was renewed and its flexibility increased in that a larger portion of the swap was freely usable for "any type of financial operation" against a backdrop of falling Argentine foreign currency reserves (Arnold, 2023a). In June 2024, the BCRA announced it had renewed a portion of its currency swap with China worth around USD \$5bn for another two years until July 2026.

2.2.1 How does a swap work at the macro level?

Formally, the PBOC and the BCRA have a reciprocal swap agreement. That means the PBOC makes RMB available to Argentina, and the BCRA makes pesos available to China. Each central bank can draw on the currency provided by the other partner and has to pay it back at the end of the drawing period (plus interest). But in practice, China has no need for pesos other than as collateral, and the agreement is unidirectional in its execution as Argentina is the only partner drawing swap funds.⁹

In effect, the swap agreement with China is a contingent credit agreement. This means that the swap line can be drawn down repeatedly by Argentina but only under certain conditions and in consultation with the PBOC. For example, the PBOC might condone the use of RMB from the swap agreement for short-term liquidity support in the face of dwindling foreign currency reserves, for repayment of external debt, or for international trade transactions such as paying for Chinese imports in RMB (Arnold, 2023a).

2.2.2 How can firms access swap funds?

If an Argentine firm wants to pay for imports in foreign currency, it needs to obtain authorization from two parties: the government through the import licensing system (Sistema de Importaciones de la República Argentina, or SIRA) as well as the BCRA.¹⁰ Urien (2022) reports that if an Argentine firm has an import order invoiced in RMB, it needs to approach the BCRA, which in turn reports the order to the PBOC to request permission to draw the relevant RMB funds from the swap line. In December 2023 the new Argentine government introduced two simplifications. The SIRA requirement was abolished and replaced with a less burdensome system (Sistema Estadístico de Importaciones, or SEDI). At the same time, the BCRA started issuing a bond (Bonos para la Reconstrucción de una Argentina Libre, or BOPREAL) to help importers pay debts to international suppliers.

To deal with RMB payments in practice, ICBC serves as a clearinghouse. ICBC has branches across more than 100 cities in Argentina. The importer may have an account with ICBC. But even

⁹A currency swap can be seen as a repurchasement agreement between central banks, functioning as a collateralized international loan. For a survey of the history and functioning of central bank currency swap arrangements, see Wiggins et al. (2023).

¹⁰Atkin et al. (2024) study the highly restrictive discretionary system of 'advanced sworn import declarations' ('Declaraciones Juradas Anticipadas de Importaciones') that was in operation from 2012-2015. From late 2015 the incoming Macri government returned to a system of automatic import licenses for most products, combined with non-automatic licenses for a subset of products.

if not, other commercial banks can administer payments with ICBC on behalf of the importer. Newspaper reports present anecdotal evidence that import authorization might be faster to obtain for RMB payments than dollar payments, even though formally this process is not supposed to depend on the invoicing currency. To the extent it happens in practice, fast-tracking RMB payments could be seen as a non-monetary subsidy of import transactions, especially of those coming from China.

2.3 Macroeconomic and political background

2.3.1 Argentina background

Our period of study coincides with a severe national foreign currency shortage. Figure 2 illustrates the overall declining trend in foreign currency reserves held by the Argentine central bank since 2018. This stretch includes a halving of reserves from over USD \$40bn at the beginning of 2023 to about USD \$20bn by the end of that year. In fact, by May 2023 Argentina's foreign currency reserves consisted to a larger extent of RMB reserves than traditional US dollar reserves.¹¹

Figure 3 further illustrates the increasing pressure on currency reserves. It shows monthly imports since 2022 compared to import payments. Payments consistently fall behind, with the gap becoming particularly large from the second half of 2023 into early 2024.

Figure 4 shows the evolution of the official and the black market exchange rates between the Argentine peso and the dollar.¹² Panel A shows a gradual devaluation of the official rate from the start of 2021 until the presidential election of 2023. At the start of 2021 the ratio of the black market and the official rate stood at about 1.5 (i.e., the black market rate was 50% higher). It increased to about 2 by the time of the election. This was an indication of the heavy restrictions on exchange rate movements imposed by Argentine authorities in combination with a growing shortage of dollars. Following the election, there was a sharp devaluation of the official rate, and the gap between the official and the black market exchange rates narrowed significantly.

Figure 5 sheds light on the increasing importance of RMB. Panel A shows the foreign exchange market volume for USD transactions, which average around USD \$2000bn per month. Panel B shows the corresponding volume for other currencies, and separately for the RMB from June 2023. At its peak the RMB volume exceeded USD \$2000bn per month before reverting dramatically to a modest level.

At the same time, macroeconomic conditions deteriorated over our period of study. Argentine

¹¹Bloomberg reports that in May 2023, swap lines with China made up the equivalent of USD \$18.8bn of reserves compared to USD \$11.5bn of Argentines' dollar bank deposits and smaller amounts of credit from the Bank of International Settlements, gold reserves, and International Monetary Fund SDRs. In a similar vein, Figure 2 in McDowell (2019) shows the currency composition of BCRA foreign exchange reserves, with the non-SDR share starting to rise in 2014 after the activation of RMB swap lines.

¹²In Argentina, the black market exchange rate is commonly referred to as the "dólar blue" and its value is quoted alongside the official rate by all newspapers and widely discussed in the media.

GDP growth was negative for six out of the eight quarters between 2022Q3 and 2024Q2. Figure 6 shows sharply rising inflation over that period, with inflation quadrupling from 71% in July 2022 to 289% in April 2024.

2.3.2 China background

Appendix Table A.1 lists the countries with which China has a bilateral swap agreement. China's bilateral swap agreements are special in that most partner countries do not have funding needs in RMB (unlike, for instance, when the Federal Reserve agrees a swap with foreign countries that have actual US dollar needs). It is therefore plausible that China's swap agreements pursue objectives that go beyond simple foreign currency liquidity needs. McDowell (2019) suggests that PBOC swap lines are a manifestation of Chinese "financial statecraft" to achieve foreign policy goals. One such goal is the reduction of China's exposure to dollar dominance in international finance, especially after the 2008/09 global financial crisis when international US dollar credit markets froze and global trade financing collapsed. This goal includes the internationalization of the RMB as a payment currency, which is hoped to bring a range of economic benefits to China, "including the reduction of exchange rate risk faced by Chinese firms, increased competitiveness of Chinese banks, and the promotion of global trade with China." McDowell (2019) states there is "very little evidence to suggest that [bilateral swap agreements] have been instrumental in promoting the use of the RMB as a currency for cross-border commercial deals." The experience of Argentina in 2023/24 is arguably novel and a departure from previous experience – albeit, as we show, a short-lived one.

It is also noteworthy that China tends to agree swap lines with countries that, compared to the average, are much more likely to experience financial and foreign exchange crises. Countries with Chinese swap lines have had currency crisis episodes in 17% of the years since 1990. Similarly, China is more likely to lend to countries that are relatively poor and that form part of the Belt and Road Initiative. As documented by Horn et al. (2021), China is now the world's largest creditor, surpassing the World Bank and the International Monetary Fund, with a strong emphasis of "south-to-south" lending to emerging economies.

Horn et al. (2023) put forward that Chinese swap lines can also be regarded as a tool allowing China to act as an international lender of last resort. They argue that China increasingly uses its global swap line network as a financial rescue mechanism to extend liquidity support to countries in financial and macroeconomic distress, e.g., those with low reserve ratios and weak credit ratings, especially if they form part of the Belt and Road Initiative.¹³ Starting in June 2023, Argentina indeed used funds drawn from the swap line to repay debt to the IMF. China thus competes with the IMF as a key lender to emerging economies, aiming to create an alternative to the dominant

¹³Argentina joined the Belt and Road Initiative in 2022. Apart from Argentina, other countries that activated RMB swap lines for short-term liquidity needs include Mongolia, Pakistan, and Turkey.

Bretton Woods institutions.

3 Data sources

To assess the determinants of invoicing currency choices of Argentine firms, we assemble a novel dataset. It is based on three main data sources: import and export transactions, bank-to-firm loans, and bank balance sheets.

Import and export transactions We use data on the universe of import transactions by Argentine firms over the period from January 2022 to June 2024. Each transaction reports the name of the importing firm, the value imported, the origin country, the HS 8-digit product code, the exact date, and the value and quantity of the transaction. Additionally and key for this paper, each transaction reports the invoicing currency used. These data are obtained from Argentina's customs agency. While we mainly focus on import transactions, in some specifications we also use data on the universe of export transactions of Argentine firms, including the identity of the exporting firms, the HS 8-digit product codes, the destination countries, the values and quantities exported, and the invoicing currencies used. As far as we are aware, our paper is the first to study the invoicing currencies of all Argentine trade with micro data at the transaction level.¹⁴

Bank-to-firm loans We also use bank-to-firm loan data. These data report all the outstanding loans that firms have with banks in Argentina in each month. We collect the data from the BCRA.¹⁵ On its website, we have to look up and download a report for each borrowing firm individually. Given this constraint, we focus on the largest 4,000 importing firms measured in terms of total imports from the world in 2022. These 4,000 firms account for 73.2% of Argentine import transactions and 81.1% of import value from China in 2022. They account for 86.8% of import transactions and 73.1% of import value from the rest of the world. The data is reported on an ongoing basis for the last 24 months from the time it is collected. We primarily use data for the period from January to December 2022. In some cases, we also use data for 2023. Loans are reported in Argentine pesos, and there is no breakdown by the currency in which loans are made. Consequently, we will note in our analysis below when the results are based on all importing firms, and when they are restricted to the largest 4,000 importers (i.e., when the bank-to-firm data is used).

Bank balance sheet data We obtain balance sheet data for each bank in Argentina from the BCRA. The data report loans in total as well as split by currency. The data distinguish between

¹⁴We use each transaction separately, but we set the time period at monthly frequency. For example, if an Argentine importing firm has multiple transactions on separate days in a given month, each transaction is a separate observation in our dataset but with the same month as the time period.

¹⁵The BCRA assembles this data from mandatory reports submitted by each agent of the financial system.

loans in Argentine pesos, US dollars, euros, Brazilian reais, and a category grouping all other currencies. We use data for 2022Q4 and 2023Q4.

Table 1 reports the list of the largest banks in our sample, measured in terms of outstanding loans in 2022. The largest lenders are the Banco de Galicia y Buenos Aires (accounting for 14.93% of outstanding loans in 2022Q4), the Banco Santander Argentina (13.31%) and the Banco BBVA Argentina (11.69%). The Industrial and Commercial Bank of China (ICBC) also stands out as an important lender, ranking sixth with a 5.98% market share.

Table 2 illustrates the variation in loans denominated in different currencies across banks. Bank lending is dominated by peso loans. The mean across banks of the share of peso loans is 92.25% in 2022Q4, ranging from 83.94% at the 10th percentile to 99.69% at the 90th percentile. The mean share of US dollar loans is 7.71%, with 0.31% and 15.89% at the 10th and 90th percentiles. The table indicates that euros and Brazilian reais account for a much smaller, almost negligible share of loans. Finally, the "other" currency category is also very small with a mean of 0.01%.

Additional datasets We use a number of supplementary datasets. The national registry of companies (Registro Nacional de Sociedades) lists all firms including their "official names" and their tax IDs. This is used to merge the customs data with the bank-to-firm loans data. The customs data also report firms' "official names," which exactly match those reported in the registry of companies. Using the registry we assign tax IDs to each firm in the customs data, and we use tax IDs to merge all datasets.

We also use data on the locations of all bank branches in Argentina. These data are obtained from the BCRA.¹⁶ In addition, we collect the locations of all firms from the national registry of companies. Thus, we can observe whether firms have access to branches of any given bank in their city or not.

In addition to Argentine trade transactions, we use equivalent data on Chile's import transactions during the same period. Like the Argentine data, the variables include the importing firm, the HS 8-digit product code, the source country, the value imported and the invoicing currency. As a neighboring country to Argentina that was not experiencing a currency crisis, Chile is used as a point of comparison.

Finally, beyond the firm-level and bank-level datasets, we obtain various macroeconomic series from the BCRA.

¹⁶The data for one out of Argentina's 24 provinces (Mendoza) are not reported in this database.

4 Empirical analysis of Argentine trade, RMB invoicing, and bank loans

4.1 Aggregate patterns for Argentine imports from China

We start by describing the aggregate patterns in the invoicing currencies used in Argentina's imports from China. Figure 7 plots the share of transactions invoiced in RMB, the share of imported value in RMB, the share of firms using the RMB (i.e., with at least one transaction in RMB), and the share of products for which RMB has been used. We observe a very large and fast transformation in the invoicing currency shares for imports from China during the months after the swap agreement with China was expanded (panel A). Between January and September 2023, the RMB share of transactions increased from 1% to 38%. Similarly, the RMB share of value grew from 0.4% to 48%. This pattern occurred across the board and was driven not solely by a few firms or a few products. By September 2023, 32% of firms and 62% of HS 8-digit products had at least some transactions invoiced in RMB.

The steep rise in RMB adoption lasted until the presidential election of 2023 (carried out in two rounds, in October and November). The election ushered in important changes in exchange rate policy and US dollar availability. The subsequent decline in RMB invoicing was similarly steep and slowed down by March 2024, at which point the RMB accounted for 9% of transactions and 13% of import value. At the same time, there was a decline in the number of firms and products associated with RMB invoicing. Our findings thus stand in sharp contrast to the notion that aggregate invoicing currency shares tend to be persistent and stable. We find here that in the context of a currency crisis and with significant government intervention, invoicing currency use can shift extremely quickly and substantially.

For further context, Table 3 reports the frequency of each invoicing currency for imports from China. In 2022 before the expansion of the swap agreement, the US dollar accounted for 95.8% of transactions, followed by the euro (2.6%) and the Argentine peso (0.8%), and with the RMB accounting for only 0.2%. Shares in terms of values were similar, and even more tilted towards the dollar.

Figure 8 complements the previous figure by plotting the number of transactions and the total value of imports by currency. It shows that the share of imports invoiced in RMB is the result of both a slow and gradual decline in imports invoiced in dollars as well as a fast and sudden rise in imports in RMB following the expanded swap agreement.

Next, we show that this pattern is unlikely a result of changes in the composition of products or importers over time. To this end, in panel B of Figure 7 we plot the probability of invoicing in RMB over time after removing firm \times HS8 product fixed effects. We find the same pattern as discussed earlier.

Figure 9 shows that this overall trend is common across all sectors of the economy. In turn,

Table 5 tabulates the HS 2-digit chapters with the highest and lowest shares of transactions invoiced in RMB at their peak in September 2023. In addition, Appendix Figure A.4 reveals that this pattern holds similarly both for differentiated and nondifferentiated products.

We also ask to what extent this pattern was driven by new or existing importers. Table 6 shows that almost all exports in September 2023 (at the peak of RMB use) are accounted for by existing firms (defined as firms that were already importing in 2022). Among transactions in RMB, 93.4% of value and 98.1% of transactions in imports from China correspond to existing firms. Among transactions in other currencies (US dollars), 95.3% of value and 95.6% of transactions in imports from China correspond to existing firms. Further, Figure 10 shows that the growth and later decline in RMB invoicing holds both for existing and new firms. Among existing firms (panel A), RMB invoicing reaches peaks of 38.7% of transactions and 47.0% of value. Among new firms (panel B), RMB invoicing reaches peaks of 28.3% of transactions and 56.1% of value.

4.2 Firms, banks, and RMB invoicing for import transactions from China

Next, we establish that importing firms' relationships with banks are key to understanding their decisions to adopt RMB as an invoicing currency.

We have two key findings. First, firms which had a bank lending relationship with the Industrial and Commercial Bank of China (ICBC) prior to the expansion of the swap agreement (i.e., in 2022) were substantially more likely to invoice in RMB subsequently. Second, firms were less likely to engage in RMB invoicing if prior to the swap expansion, they had a lending relationship with banks that had a higher dollar share in their loan portfolio. Quantitatively, we find that these two elements explain a meaningful share of the variation in invoicing currency use across firms. We first present some descriptive evidence and then proceed sequentially to discuss each of these findings.

To start, Figure 11 presents descriptive evidence on the variation of invoicing patterns across firms. Panels A and B distinguish between small and large importers (where we use their total imports as a proxy for their size). The sample is split based on firms' total (worldwide) imports in 2022 (i.e., before the swap agreement was expanded) such that half of the import transactions fall into each subsample.¹⁷ Panel A plots raw data, and panel B removes firm × HS8 product fixed effects. In both cases, there is a large difference in RMB adoption in favor of large importers. By September 2023, the share of transactions invoiced in RMB is 50.3% for large importers and 24.4% for small ones, based on panel A. By the end of our sample, large importers are still more likely to invoice in RMB (14.1% vs. 2.0%). A straightforward interpretation of this result is that there is a fixed cost associated with adopting RMB as an invoicing currency, and large firms are more likely to afford this cost. Amiti et al. (2022) discuss the extension of their baseline invoicing

¹⁷Similar results are obtained when we split the sample such that half of the firms are in each subsample. See Appendix Figure A.1.

model with this type of fixed cost. It could be associated with using RMB specifically (perhaps due to macroeconomic and political risk or a historical preference against RMB). This fixed cost could also be associated with adding any new currency: firms could benefit from using the same currency across markets.

Panel C and D in the same figure split firms into those with and without a banking relationship with ICBC in the period before the expansion of the swap agreement (i.e., in 2022). Again, panel C plots the raw share of transactions in RMB and panel D removes fixed effects. Both figures indicate that firms with ICBC loans before the agreement were substantially more likely to switch to RMB after the expansion was signed. By September 2023, the share of transactions invoiced in RMB stood at 56.0% for firms with an ICBC banking relationship compared to less than half (23.3%) for the rest. Recall from the discussion in Section 2 that all banks in Argentina – not just ICBC – were eligible to provide firms with RMB after the swap agreement was expanded, without any extra cost. This finding, which we establish more formally below, speaks to the persistence of banking relationships. It may also suggest that ICBC had more detailed information on the practicalities of RMB invoicing or an incentive, political or otherwise, to encourage their clients to adopt the new invoicing currency.

Next, we more formally assess the ICBC role in shaping firms' invoicing choices after the swap expansion. We estimate the following probability model:

$$RMB_{mfpct} = \beta_1 \ln FirmSize_f + \beta_2 ICBC_f + \delta_p + \delta_t + \epsilon_{mfpct}, \tag{1}$$

where the dependent variable RMB_{mfpct} is equal to one if import transaction *m* by firm *f* in product *p* from country *c* at time *t* is invoiced in RMB, and zero otherwise.¹⁸ The time period is a month, with the sample running from January 2022 to June 2024. At this point, we restrict the sample to import transactions from China such that *c=China* for all observations. The variable $\ln FirmSize_f$ captures the size of the importing firm measured by its total worldwide imports in 2022 (in logs). The term $ICBC_f$ is a dummy variable equal to one for a firm with a loan from ICBC in 2022 (i.e., before the agreement was expanded). The regression also includes product fixed effects δ_p at the HS 8-digit level and time (year-month) fixed effects δ_t . Standard errors are clustered by firm and HS8 product using multiway clustering. Given the various fixed effects, we estimate this regression as a linear probability model with OLS.

The results are shown in Table 7. In columns 1 through 3, the estimation is based on the period from January 2023 to June 2024. Column 1 only includes firm size, column 2 only includes the $ICBC_f$ dummy variable, and column 3 includes both. First, the results indicate that larger importers are more likely to invoice in RMB. Based on column 3, the difference between the 10th and 90th percentiles of firm size is associated with a 23.9 percentage point higher probability of

¹⁸Recall that all transactions not invoiced in RMB are almost always invoiced in US dollars.

invoicing imports in RMB.¹⁹ Second, firms with an ICBC relationship before the swap expansion are substantially (8.8 percentage points) more likely to invoice in RMB. This is equivalent to more than 40% of the unconditional probability of invoicing in RMB during the sample period, which is 0.2. In column 4 we repeat the estimation focusing on the shorter period from January 2023 to September 2023, which is the period witnessing a surge in RMB use. We find essentially the same pattern.²⁰

As a robustness check, we use spatial data on the location of all firms and ICBC branches. Instead of using a dummy variable as above capturing whether a banking relationship with ICBC existed, we construct a dummy variable equal to one for firms in the same city as an ICBC branch, and zero otherwise. It is worth noting that ICBC branches are widespread across Argentina with over 100 branches in total. We then estimate a specification equivalent to (1) but replace the ICBC dummy with this new dummy variable. For tighter identification, we include province fixed effects to compare firms across cities within provinces. The results are shown in Table 8 and indicate that the coefficient for having an ICBC branch is positive and statistically significant, with a similar magnitude to the coefficient for having a banking relationship with ICBC. This robustness check provides further evidence of the association between firms' having a banking relationship with ICBC in 2022 and using RMB for invoicing in 2023.

Next, we show how importing firms' invoicing currency choices are also shaped by the availability of dollars, or lack thereof. Specifically, we establish that firms were less likely to use RMB as an invoicing currency when they had a pre-swap expansion relationship with banks with a higher US dollar share in their loan portfolio. Recall from the discussion in Section 2.3 that during 2023, and especially in the second half of the year, the currency crisis and the dollar shortage worsened as evidenced by the increasing gap between the official and black market exchange rates. To this end, we use the bank balance sheet data corresponding to the last quarter of 2022. For each bank in the sample, we define the US dollar share of loans as the ratio of dollar loans over total loans. We then compute, for each importing firm, a weighted average of these bank-level shares across the banks the firm has relationships with. If we define weights ω_{bf} as the ratio of the loans of firm f with bank b over the total loans of firm f with all banks, both measured in 2022, then we obtain:

$$USD \ loan \ share_f = \sum_{b \in f} \omega_{bf} USD \ loan \ share_b, \tag{2}$$

where $b \in f$ indicates summing over the set of banks *b* which have an outstanding loan to firm *f*. Note that because we do not observe the currencies of individual loan agreements between

¹⁹The 10th and 90th percentiles of (log) firm size are 13.8 and 18.8.

²⁰In Appendix Table A.2 we estimate a version of specification (1) with product-time fixed effects δ_{pt} . The results are very similar.

banks and firms, the implicit assumption in this measure is that the bank-level dollar loan share is applied proportionally across firms.

We then extend the earlier specification (1) to include this new variable:

$$RMB_{mfpct} = \beta_1 \ln FirmSize_f + \beta_2 ICBC_f + \beta_3 USD \ loan \ share_f + \delta_p + \delta_t + \epsilon_{mfpct}.$$
(3)

The results are reported in Table 9. In column 1 the sample goes from January 2023 to June 2024. The coefficients on $\ln FirmSize_f$ and the $ICBC_f$ dummy variable are similar to those in the previous table. The negative coefficient on USD loan share_f indicates that firms are less likely to use RMB if they have pre-swap expansion relationships with banks with high dollar loan shares. The interpretation is that during this period of currency crisis and dollar shortage, relationships with banks that lend more in dollars allow firms easier access to dollars for importing, reducing the need for RMB. The magnitude of the coefficient is such that moving from the 10th to the 90th percentile of the USD loan share_f measure is associated with a decline of 6.1 percentage points in the probability of invoicing in RMB.²¹ In column 2 we replace the USD loan share_f measure by another version using the combined share of US dollars, euros and Brazilian reais.²² The coefficients are very close to those in column 1. Columns 3 and 4 are equivalent, but with the difference that the sample goes from January 2023 to September 2023 (i.e., the period during which RMB use grows rapidly). The coefficient on USD loan share_f is in the same ballpark as the one based on the longer sample, albeit somewhat smaller.²³

Since there was variation over time in the shortage of dollars (as implied by the gap between the official and black market exchange rates), we examine how the above coefficients vary over time. Recall that the currency crisis worsened in the second half of 2023 and eased to some extent in 2024. We revisit the estimation of equation (3) by interacting each of the three terms with dummy variables for each quarter between 2023Q1 and 2024Q2.

The results are shown in Table 10. The effect of the USD loan share_f variable is most negative and statistically significant in the last two quarters of 2023 when the currency crisis was at its most profound. This effect is U-shaped, with a negative but smaller effect before and after those two quarters. This is consistent with the timing of the crisis and provides further evidence of a link between the dollar shortage and the invoicing decisions of firms. For the last quarter of 2023, the magnitude of the coefficient is roughly twice as large as that found in Table 9 for the average of the entire period. We find a very similar pattern in column 2 where the measure of dollar shortage is constructed with the combined loan share of dollars, euros and Brazilian reais.

²¹The 10th and 90th percentiles of the USD loan share $_f$ measure are 0.051 and 0.139.

²²We denote this variable as USD+EUR+BRL loan share_f. Apart from US dollars, euros and Brazilian reais are traditionally the only quantitatively relevant foreign currencies for invoicing. But recall from the summary statistics in Table 2 that euros, and Brazilian reais account for a very small fraction of loans in our sample.

²³In Appendix Table A.2 we estimate a version of specification (3) with product-time fixed effects δ_{pt} . The results are very similar.

We also see in this table that the dummy capturing pre-swap expansion relationships with ICBC is close to zero in the first quarter of 2023 and becomes larger and statistically significant starting in the third quarter of that year, remaining relatively constant afterwards. This is consistent with the timing of the implementation of the RMB invoicing system following the swap agreement expansion.

In summary, we interpret our findings as evidence of a foreign currency shortage mechanism. That is, at the beginning of our data period in early 2023, Argentina was facing a severe dollar shortage, rationing access of Argentine businesses to foreign currency. The RMB swap expansion was used to alleviate this foreign currency shortage. But unlike during previous swap agreements, this time around the Argentine authorities did not convert RMB into dollars but rather kept RMB on the balance sheet. As long as the country was facing a dollar shortage, RMB was used as a foreign currency substitute. But once the dollar shortage was alleviated in the wake of Milei's reforms, the importance of RMB waned and businesses reverted to using dollars. Reasons for RMB aversion relative to the dollar are likely to include the lack of existing RMB adoption across industries, the lack of deep and liquid global financial markets including payment infrastructure, the lack of free RMB convertibility, and Chinese capital controls.²⁴

Finally, it is worth pointing out that the changes in RMB invoicing do not seem to go hand in hand with changes in the currency of loans from banks to firms. Table 2 reports statistics for the distribution of loan shares by currency across banks. It compares 2022Q4 (panel A) to 2023Q4 (panel B). We see little change over time. For example, the mean across banks of the loan share in dollars is 92.25% in 2022Q4 and 90.25% in 2023Q4. Loans in RMB are part of the "other" category, and the mean across banks in this category goes from 0.01% to 0.03%. While this might imply a change in RMB loans, it would have been very small and hardly a relevant driver of the switch in invoicing currencies.

4.3 RMB invoicing for import transactions from the rest of the world

We now examine the use of RMB in imports from the rest of the world. We find that at the same time that RMB use increases for imports from China, the RMB starts being used in imports from the rest of the world but to a lesser extent.

²⁴However, Eichengreen et al. (2024) argue that even in the absence of full financial liberalization, the RMB could still play a more important role as international currency. But this would require policy support, in particular convertibility of RMB into dollars on offshore markets. In contrast, Prasad (2017) highlights the long-term limits that undermine the RMB's rise towards establishing itself as a global payment and reserve currency. China would have to embark on reforms fostering a more open and transparent system of government with a reliable institutional framework including stronger rule of law and tighter property rights. One short-term argument in favor of using RMB as a payment currency might be the weakness of domestic currency against the dollar. For example, in 2023 Bangladesh agreed to make a large payment to Russia in RMB and "opted against using the US dollar because its currency has fallen sharply against it" while also noting that Russia had been largely frozen out of US dollar payment systems after its 2022 invasion of Ukraine (Source: China Southern Morning Post, 21 April 2023). Another reason against the dollar could be the potential exposure to US monetary policy cycles, in particular aggressive US tightening in the wake of Covid-19 and the associated rise in US dollar borrowing costs (Source: China Southern Morning Post, 27 April 2023).

Figure 12 reports the transaction share and value share invoiced in RMB for imports from all countries except China. Concurrently with the increase in RMB use for imports from China, we observe an increase in its adoption for imports from the rest of the world. The RMB transaction and value shares go up from 0% in January 2023 to 1.7% and 2.9%, respectively, by September 2023.²⁵ Like for imports from China, there is a decline in RMB use after the presidential election in the final months of 2023 and in 2024. To provide more context, Table 11 tabulates the frequency of each invoicing currency in imports from the rest of the world. In 2022, before the swap agreement expansion, the US dollar accounts for 84.4% of transactions, followed by the euro (9.4%), the Argentine peso (3.5%), and the Brazilian real (1.2%). Table 12 lists the countries that reach the highest transaction and value shares invoiced in RMB at their peak in September 2023. Most countries in the list are in Africa and Asia. For example, 23% of transactions and 15% of value imported from South Korea are invoiced in RMB at this point.

We find a link at the firm level between RMB use in imports from China and the rest of the world. This can be seen in Figure 13 where we plot the RMB transaction share and the RMB value share among imports from the rest of the world. We also split the sample between firms that import any positive amount from China invoiced in RMB in the current month versus firms that do not. At its peak, the RMB transaction share reaches 5% for firms that also import any amount from China. In contrast, this share reaches less than 2% for the rest of firms. In terms of value, firms that import from China reach a 9% RMB share in imports from the rest of the world, while for firms that do not import from China this share is about 3%.

This insight can be shown more formally with the following regression:

$$RMB_{mfpct} = \beta_1 \ln FirmSize_f + \beta_2 Importer in RMB from China_{ft} + \delta_{pc} + \delta_t + \epsilon_{mfpct}.$$
(4)

The sample is imports from the rest of the world, and the dependent variable is a dummy equal to one for transactions invoiced in RMB. The regressor of interest, *Importer in RMB from China_{ft}*, is equal to one for firms that import any amount from China invoiced in RMB in the current month, and zero otherwise. The regression also includes country × HS8 product fixed effects δ_{pc} and time dummies δ_t . Standard errors are clustered by firm, HS8 product, and country using multiway clustering.

The results are reported in Table 13. Column 1 considers the period from January 2023 to June 2024, while column 2 restricts the sample to the period from January 2023 to September 2023. In both cases, the coefficients are very similar. Based on column 1, the probability of invoicing in RMB from the rest of the world is 4.4 percentage points higher for firms that import any positive amount from China invoicing in RMB during the same month. This difference is six times larger

²⁵The gap between the RMB share in terms of transactions and value suggests that larger transactions are more likely to be invoiced in RMB. For further context, Appendix Figure A.2 plots the number of transactions and the total value of imports by currency.

than the unconditional mean of the dependent variable during this period (0.007).

In the case of imports from the rest of the world, we also find a link between the probability of invoicing in RMB and firms' relationships with ICBC in 2022 (prior to the swap expansion). We also associate it with the dollar loan share of firms' banking relationships in 2022. To this end, we estimate the below regression akin to equation (3) using the rest of the world sample. The only difference is that the HS8 product fixed effects are replaced by HS8 product \times country fixed effects and the standard errors are now clustered by firm, HS8 product, and country using multiway clustering:

$$RMB_{mfpct} = \beta_1 \ln FirmSize_f + \beta_2 ICBC_f + \beta_3 USD \ loan \ share_f + \delta_{pc} + \delta_t + \epsilon_{mfpct}.$$
(5)

The results are shown in Table 14. Columns 1 and 2 correspond to the period from January 2023 to June 2024, while columns 3 and 4 restrict the sample to the period from January 2023 to September 2023. In the longer period, we find that a pre-swap expansion relationship with ICBC is associated with a 0.5 percentage point higher probability of invoicing in RMB. This is a large effect, comparable to the 0.007 (0.7 percentage point) unconditional probability of invoicing in RMB during the period. We also find that firms with pre-expansion relationships with banks with higher dollar loan shares are less likely to invoice in RMB. Specifically, moving from the 10th to the 90th percentile of the *USD loan share*_f measure is associated with a decline of 0.17 percentage points in the probability of invoicing in RMB, based on column 2 or 4.²⁶ This is a large effect as it is roughly half the average probability of RMB invoicing in the regression sample of column 2. In columns 5 and 6, we add the dummy variable for firms that also import in RMB from China. We continue to see the higher likelihood of importing in RMB from the rest of the world for firms that import in RMB from China. We also see that banking relationships, captured by the *USD loan share*_f variable, continue to have a statistically significant association.

Another point to consider is that China has signed similar swap agreements with many, typically developing, countries. It might seem plausible that RMB use is more frequent for imports from these countries. However, we do not find evidence in favor of this hypothesis. We split the rest-of-the-world sample into countries with and without swap agreements with China.²⁷ Figure 14 plots the shares of import transactions and values invoiced in RMB for each group. There is no clear difference between them.

4.4 The role of exports

Next, we show that RMB use does not spread to Argentine firms' exports. We find absolutely no use of RMB in Argentine firms' exports. Table 4 describes the frequency of invoicing currencies in Ar-

²⁶This coefficient is statistically significant during the January 2023 - September 2023 period, and marginally not so during the longer period.

²⁷The list of countries with swap agreements with China is provided in Appendix Table A.1.

gentine exports, which are largely dominated by the US dollar. This result is to be expected. Amid the dollar shortage experienced by the Argentine economy, export revenue is the main source of new dollars, so the incentive is to keep invoicing in dollars.

We also show that exporting activity has an impact on the invoicing currency used for imports from China. For this purpose, we first augment equation (3) by adding a dummy variable for firms that are exporters to China and a separate dummy for firms that export to the rest of the world. Just like with earlier variables, we measure export status in 2022 before the swap expansion.

The results are shown in Table 15. In column 3, we include firms' total imports (the measure $\ln Size_f$ used previously), a dummy variable for exporters to China, and a dummy variable for exporters to the rest of the world. We find, as before, that larger firms are more likely to use RMB.²⁸ The new result here is that firms that export to the rest of the world are less likely to invoice imports from China in RMB. By contrast, exporting to China is not associated with a lower probability of invoicing in RMB. Columns 1 and 2 introduce these exporting dummy variables sequentially, with similar results. Specifically, a firm that exports to the rest of the world (but not to China) has a 13 percentage point lower probability of invoicing in RMB.²⁹

In column 4, we add the variables that capture firms' banking relationships, as explored earlier. We still find that the measures capturing the pre-swap agreement banking relationships with ICBC and the dollar loan shares of firms' banks are statistically significant and have similar magnitudes compared to the results reported earlier in Table 9. Thus, the export mechanism does not appear to reduce the importance of the banking mechanism.

Finally, in column 5 we restrict the sample to firms that export (anywhere) and use measures of export intensity instead of dummy variables for exporting activity. Specifically, we include (log) total exports and the share of exports to China. The results point in a similar direction. The coefficient on (log) total exports is negative, while the coefficient on the share of exports to China is positive.

4.5 Evidence from Chilean firms

To further strengthen the evidence of a link between macroeconomic conditions in Argentina and firms' invoicing currency choices, we additionally consider firm-level data from neighboring Chile. That is, we compare the invoicing patterns by Chilean firms for imports from China to those of Argentine firms. While Chile signed a swap agreement with China in 2015, Chile did not face a currency crisis during the 2023-2024 period under study.³⁰ We show below that while both Chile and Argentina traditionally invoice imports from China almost exclusively in US dollars, we

²⁸The magnitude of this coefficient is similar to that found earlier in Table 9.

²⁹A firm that exports to both the rest of the world and China has an 11 percentage point lower probability of invoicing imports from China in RMB.

³⁰The swap agreement between the Central Bank of Chile and the PBOC was originally established in 2015 and renewed in 2020.

observe the temporary switch to RMB described earlier only among Argentine importers.

To this end, we assemble equivalent data on imports transactions of Chilean firms. We then pool the data on import transactions from China for all importing firms in both countries. First, as context, Figure 15, plots the share of Chilean import transactions from China. The share of transactions invoiced in RMB hovers around 1% or less and does not increase over time. This is a first indication that the patterns described earlier are unique to Argentina.

We also provide more formal econometric evidence by estimating the following regression using the pooled sample for both countries:

$$RMB_{mfpst} = \beta \cdot ARGENTINA_s + \delta_{fps} + \delta_t + \epsilon_{mfpst}, \qquad (6)$$

where *s* refers to the importing country (either Argentina or Chile). The term *ARGENTINA_s* is a dummy variable equal to one for imports from Argentina and zero for imports from Chile. We include fixed effects δ_{fps} by firm $f \times \text{product } p \times \text{importing country } s$ as well as time dummies δ_t . Only for this comparison with Chile, products are now defined at the HS6 level since this is the most disaggregated level comparable across countries. Standard errors are clustered by importing country and by HS6 product using multiway clustering.

Table 16 reports the results. The coefficient in column 1 indicates that on average over the whole period, Argentine firms are 13.3 percentage points more likely than Chilean firms to invoice imports from China in RMB. In column 2, we extend this regression by introducing interaction terms between the dummy variable $ARGENTINA_s$ and dummies for each quarter. The coefficients in column 2 indicate that the differential adoption of RMB invoicing by Argentine relative to Chilean importers follows the same pattern of growth and decline that we documented earlier. That is, RMB adoption peaks in the last quarter of 2023 and drops afterwards.

These results further corroborate the hypothesis that the temporary shift in Argentina of invoicing currency away from the US dollar towards RMB was brought about by the BCRA's swap expansion with China in combination with the concurrent dollar shortage.

4.6 **RMB** use and trade volumes

To what extent did the switch to RMB impact the volume of imports from China? Anecdotal evidence indicates that the dollar shortage was limiting the ability of firms to import, so we would expect the availability of RMB to ease this constraint and increase trade volumes.³¹

To this end, we estimate the following regression in which the dependent variable is the log of

³¹For context, Appendix Figure A.3 plots time series of imports from China and the rest of the world between January 2022 and June 2024.

imports from China by firm *f* at time (year-month) *t*:

$$\ln ImportValue_{ft} = \sum_{t} \beta_t RMB_f + \delta_f + \delta_t + \epsilon_{ft}.$$
(7)

The indicator variable RMB_f is equal to one for firms using the RMB at any point after January 2023. The term $\sum_t \beta_t RMB_f$ corresponds to the interaction between the RMB dummy variable and time dummies. Thus, the coefficients of interest β_t capture the differential path of Chinese imports by Argentine firms that did or did not use RMB. The regression includes firm fixed effects δ_f and time fixed effects δ_t . In some specifications, we also control for the interaction between the firm's sector (measured as the main HS2 category imported) and time dummies (not shown in the equation above).

The estimated coefficients on the interaction terms are plotted in Figure 16. Panel A corresponds to the baseline specification. We see a clear increase in imports from China starting around mid-2023. As discussed earlier, this is the time when RMB invoicing becomes popular for imports from China. This increase in imports from China deviates clearly from the trend seen in previous months. We also see that imports from China fall back to the previous trend in early 2024. It is at the start of the new administration that we see RMB invoicing decline and the dollar shortage ease. The magnitude of the coefficients indicates a roughly 20% increase in imports from China during this period. Overall, the figure suggests a clear correspondence between RMB invoicing and the import volume from China.

As a robustness check, panel B repeats the estimation incorporating additional fixed effects. In this case, we control for the interaction of sector fixed effects (corresponding to each firm's main HS2 category imported) and time dummies. This means we compare firms with and without RMB invoicing but within the same sector. The results are very similar to those in panel A. As an additional robustness check, in panel C we use a higher cutoff to classify a firm as invoicing in RMB. In this case, the RMB indicator variable is equal to one for firms that have at least 30% of their transactions invoiced in RMB after January 2023. We again see a temporary increase in imports from China associated with RMB use, with similar timing and magnitude as before.

Next, we ask whether the increase in imports from China for firms invoicing in RMB is associated with a change in their imports from the rest of the world. On the one hand, there could be a redirection of imports towards China as the availability of RMB makes importing from China easier. On the other hand, these firms might also be using RMB in imports from the rest of the world as we saw earlier, making it easier to import more from everywhere. To assess this idea, we estimate equation (7) using the sample of imports from the rest of the world (and excluding imports from China). The RMB_f dummy variable on the right-hand side is defined in the same way as before, i.e., it is equal to one for firms using RMB to any extent in their imports from China at any point after January 2023. The results are shown graphically in Figure 17. In this case, there is less evidence of a statistically significant pattern. If anything, the figures show an increase in imports from the rest of the world during the period when RMB use is higher, in particular in the specifications of panels A and B. This implies that the rising imports from China for firms using RMB shown earlier are not the result of diversion away from the rest of the world. In summary, RMB use is associated with an increase in total imports, which is consistent with the notion that RMB provision eases the lack of foreign currency availability for invoicing purposes, and that this shortage was restricting imports.

5 Conclusion

A substantial fraction of transactions in international trade is invoiced in a vehicle currency. The vast majority of such transactions is invoiced in US dollars, and a few in euros. At the same time, China has announced the objective of the internationalization of the RMB, including for international trade invoicing. But how can these efforts gain traction?

We examine micro data for import and export transactions of Argentine firms over the period from 2022 to 2024. Argentine trade has traditionally been invoiced almost exclusively in US dollars. But starting in early 2023, we observe a sharp rise of RMB invoicing for import transactions from China, and to a lesser extent also from third countries such as Egypt and Vietnam, mainly driven by large Argentine importers. The rise in RMB invoicing is associated with a noticeable increase in trade volumes, with no apparent diversion of trade from other partners. We argue that such a sharp rise of a new invoicing currency is highly unusual in both speed and magnitude. However, we find no evidence of RMB invoicing adoption for export transactions from Argentina. As a comparison, we also consider invoicing choices for importers from Chile, a neighboring country with no concurrent macroeconomic crisis. We find no evidence of RMB adoption for their invoicing choices.

We use bank-firm lending data to link the rise of RMB invoicing to a swap expansion by the Chinese central bank with the Argentine central bank. We find that RMB invoicing is associated with borrowing from a major Chinese state-owned commercial bank active in Argentina. Our results support the notion that the RMB swap expansion alleviated the rationing of foreign currency in the context of dwindling US dollar reserves held by the Argentine central bank. Once Javier Milei was elected as the new president of Argentina in the fall of 2023, exchange rate controls were loosened, and RMB invoicing quickly receded.

Our results shed new light on firms' invoicing currency choices. We show that in contrast to the prevalent view, invoicing currency patterns can shift rapidly. But they are contingent on the macroeconomic context in general and foreign currency shortages in particular. Chinese efforts to internationalize the RMB have been partly successful in Argentina but they have not persisted.

Nevertheless, our results support the view that the internationalization of the RMB may be possible if backed up by appropriate institutional arrangements, especially central bank liquidity and commercial bank lending.

Notes: This graph shows the share of Argentine imports from China (panel A) and the share of Argentine exports to China (panel B) at annual frequency between 1995 and 2023. The data are obtained from the United Nation's Comtrade database.

Notes: These are (gross) international reserves at the BCRA (downloaded directly from their website).

Notes: Source: BCRA.

Notes: Panel A shows the official and black market exchange rates between the Argentine peso and the US dollar. Panel B shows the difference between the black market and the official exchange rates. The black market exchange rate is widely called "dólar blue."

Notes: Source: BCRA. Panel A shows the foreign exchange market volume for US dollars. In panel B, the "Other (incl. RMB)" category includes all currencies except the US dollar and the euro up to May 2023. Reporting changes in June 2023 when the RMB becomes a separate category so that the "Other (excl. RMB)" category includes all currencies except the US dollar, the euro, and the RMB.

Notes: This figure shows the 12-month percent change in the consumer price index as reported by Argentina's statistical institute (INDEC).

Notes: Panel A shows the share of transactions and the share of value invoiced in RMB in imports from China. Panel B shows estimated time dummies from a regression using transaction-level data on imports from China in which the dependent variable is a dummy variable for transactions invoiced in RMB and including time dummies and firm \times HS8 product fixed effects. Panel C shows the share of firms with at least one transaction in RMB. Panel D shows the share of HS 8-digit products with at least one transaction in RMB.

Notes: Panel A shows the number of transactions (in thousands) invoiced in RMB, US dollars, and other currencies. Panel B shows the value of imports (in million US dollars) invoiced in RMB, US dollars, and other currencies.

Notes: This figure shows estimated time dummies from a regression using transaction-level data on imports from China in which the dependent variable is a dummy variable for transactions invoiced in RMB and including time dummies and product fixed effects. The legend indicates the HS 2-digit chapters in each sector.

A) Share of transactions and value in RMB: Existing firms

B) Share of transactions and value in RMB: New firms

Notes: Both panels shows the share of transactions and the share of value invoiced in RMB in imports from China. Panel A corresponds to existing firms, defined as those exporting in 2022. Panel B corresponds to new firms, defined as those with no exports in 2022.

A) By importer size: Share of transactions in RMB B) By importer size: RMB invoicing probability

Notes: Panel A shows the share of import transactions from China invoiced in RMB for small and large importers. Importer size is measured as total imports from the world in 2022. These categories are defined such that half of the transactions belong to each group. Panel B shows estimated time dummies from a regression using transaction-level data on imports from China in which the dependent variable is a dummy variable for transactions invoiced in RMB and including time dummies and firm × HS8 product fixed effects. This regression is estimated separately for small and large importers. Panel C shows the share of import transactions from China invoiced in RMB for importers with and without a banking relationship with ICBC in 2022. Panel D shows estimated time dummies from a regression using transactions invoiced in RMB and including time dummies and firm × HS8 product fixed effects. This regression is estimated for transactions invoiced in RMB for importers with and without a banking relationship with ICBC in 2022. Panel D shows estimated time dummies from a regression using transaction-level data on imports from China in which the dependent variable is a dummy variable for transactions invoiced in RMB and including time dummies and firm × HS8 product fixed effects. This regression is estimated separately for importers with and without a banking relationship with ICBC. In panels C and D, the sample is restricted to firms in the bank-to-firm loans data.

Figure 12: RMB invoicing for imports from the rest of the world

Notes: Panel A shows the share of transactions and the share of value invoiced in RMB. Panel B shows estimated time dummies from a regression using transaction-level data on imports from China in which the dependent variable is a dummy variable for transactions invoiced in RMB and including time dummies and product fixed effects.

Notes: Panel A shows the share of transactions invoiced in RMB for imports from the rest of the world (i.e., all countries excluding China). Panel B shows the share of value invoiced in RMB for imports from the rest of the world. In both panels the solid black line corresponds to firms with imports from China invoiced in RMB in the same month. The dashed blue line corresponds to the rest of the firms.

Figure 14: RMB invoicing for imports from the rest of the world: The role of swap agreements with China

Notes: This figure shows estimated time dummies from a regression using transaction-level data on imports from the rest of the world in which the dependent variable is a dummy variable for transactions invoiced in RMB and including time dummies and firm × HS8 product × country fixed effects. The sample is split between source countries with and without swap agreements with China.

Notes: This figure shows the share of transactions invoiced in RMB in Chilean imports from China (panel A) and Argentine imports from China (panel B).

Figure 16: RMB invoicing and import volumes from China

C) With sector × time fixed effects and higher cutoff for RMB

Notes: Each panel shows estimated time dummies from specification (7) using the sample of imports from China. Panel A corresponds to the baseline specification described in the main text. Panel B adds sector × time fixed effects, with the sector defined as the main HS2 imported by the firm. Panel C also includes these additional fixed effects, and the RMB dummy variable is equal to one for firms with more than 30% of transactions in RMB after January 2023.

C) With sector × time fixed effects and higher cutoff for RMB

Notes: Each panel shows estimated time dummies from specification (7) using the sample of imports from the rest of the world. Panel A corresponds to the baseline specification described in the main text. Panel B adds sector × time fixed effects, with the sector defined as the main HS2 imported by the firm. Panel C also includes these additional fixed effects, and the RMB dummy variable is equal to one for firms with more than 30% of transactions in RMB after January 2023.

Bank name	Market share (2022Q4)
Banco de Galicia y Buenos Aires S.A.U.	14.93%
Banco Santander Argentina S.A.	13.31%
Banco BBVA Argentina S.A.	11.69%
Banco de la Nación Argentina	7.27%
Banco Credicoop Cooperativo Limitado	6.03%
Industrial and Commercial Bank of China (ICBC)	5.98%

Table 2: Summary statistics for loan shares by currency based on bank balance sheets

Notes: This table reports summary statistics for the distribution of loan shares by currency across banks in 2022Q4 and 2023Q4. For example, the cell in the first row, first column of panel A indicates that the mean across banks of the share of loans in Argentine pesos is 92.25%, while the cell in the fifth row in the first column indicates that the 50th percentile is 95.24%. These summary statistics are not weighted by bank size. The currencies in the first four columns are reported individually in the bank balance sheets. All other currencies in bank balance sheets are grouped.

	Share of transactions				Sh	are of val	lue
	2022	2023	2024	-	2022	2023	2024
US dollar	95.8%	74.9%	82.1%		98.2%	70.9%	82.5%

Table 7: Probability of RMB invoicing for imports from China: Firm-level determinants

Notes: This table reports the results of estimating specification (1). Each observation corresponds to an import transaction from China. The dependent variable is equal to one for transactions invoiced in RMB, and zero otherwise. In columns 1 through 3 the sample consists of all transactions between January 2023 and June 2024. In column 4 the sample consists of all transactions between January 2023. Standard errors are clustered by firm and HS8 product using multiway clustering. ***, **, and * indicate statistical significance at the 1%, 5%, and 10% level.

Table 8: Probability of RMB invoicing for imports from China: Firm-level determinants

Notes: This table reports the results of estimating specification (1). In column 1 we use the dummy variable indicating a banking relationship with ICBC. In column 2 we replace it with a dummy variable indicating whether a firm is located in a city with an ICBC branch. Each observation corresponds to an import transaction from China. The dependent variable is equal to one for transactions invoiced in RMB, and zero otherwise. In all columns the sample consists of all transactions between January 2023 and June 2024. Standard errors are clustered by firm, HS8 product, and province using multiway clustering. ***, **, and * indicate statistical significance at the 1%, 5%, and 10% level.

Table 10: Probability of RMB invoicing for imports from China: Firm-level determinants with time-varying coefficients

Notes: This table reports the results of estimating specification (3) where we allow the coefficients of the explanatory variables to vary by quarter (2023Q1-2024Q2). Each observation corresponds to an import transaction from China between January 2023 and June 2024. The dependent variable is equal to one for transactions invoiced in RMB, and zero otherwise. Standard errors are clustered by firm and HS8 product using multiway clustering. ***, **, and * indicate statistical significance at the 1%, 5%, and 10% level.

Table 16: Probability of RMB invoicing for imports from China: Argentine vs. Chilean importers

Notes: This table reports the results of estimating equation (6). Each observation corresponds to an import transaction from China either from Argentina or Chile between January 2023 and June 2024. The dependent variable is equal to one for transactions invoiced in RMB, and zero otherwise. Standard errors are clustered by importing country and HS6 product using multiway clustering. ***, **, and * indicate statistical significance at the 1%, 5%, and 10% level.

A Appendix

A.1 Timeline of China-Argentina currency swaps and key events

Below we provide a timeline with key dates on the history of China-Argentina currency swaps, drawn from various newspaper articles for the most recent events as well as Horn et al. (2023) and (Arnold, 2023a) for earlier events.

- April 2009: Argentina and China initiate their first a bilateral swap agreement worth RMB 70bn (USD \$11bn). It remains dormant for three years without being drawn down. Source: Bloomberg, 26 June 2023.
- July 2014: Following its sovereign debt default, Argentina extends its swap agreement for an additional three years.
- October 2014: Argentina starts drawing down swap lines and begins serial rollovers, borrowing close to USD \$11bn by October 2015, representing about 40% of Argentina's foreign currency reserves.
- 2018: Argentina and China agree to increase the swap line from RMB 70bn to RMB 130bn (USD \$19bn).
- December 2018: Argentina draws an additional RMB 60bn (USD \$8.7bn) from the swap line, bringing its total outstanding swap debt to USD \$18.9bn.
- December 2021: Argentina's total PBOC swap debt increases to USD \$20.5bn, representing 51.6% of the BCRA's foreign currency reserves. See Arnold (2023b).
- October 2022: The Argentine government creates the Sistema de Importaciones de la República Argentina (SIRA), a new import licensing system.
- November 2022: The PBOC expands its currency swap agreement with Argentina by RMB 35bn (roughly USD \$5 billion) to RMB 165bn. See Arnold (2023b).
- March 2023: Seen as a milestone in China's efforts to internationalize the use of its currency, the RMB surpasses the US dollar for the first time as the most widely used currency for cross-border transactions in China (covering both the current and capital accounts). The RMB was used in 48% of cross-border transactions, and the dollar was used in 47%. (Source: Reuters 20230426.)
- April 2023: On a visit to China, Brazilian President Luiz Inácio Lula da Silva questions the use of "US dollars for settlements and not the yuan or other international currencies"

and calls on BRICS countries (Brazil, Russia, India, China, and South Africa) to settle bilateral trade and investments in their own currencies. Source: (China Southern Morning Post 20230421 and 20230427.)

- May 2023: The Argentine aggregate monthly trade deficit for May reaches its largest extent (USD \$1.2bn) since 2018. Source: Bloomberg 20230626. Minister of Economy Sergio Massa blames the drought for having USD \$15bn less in dollar income due to reduced agricultural exports. (Source: El País 20230426.)
- June 2023: The Chinese swap line is renewed, standing at RMB 130bn in total (USD \$19bn). The portion that can be used freely for "any type of financial operation" is doubled to RMB 70bn. The dollar reserves of the Argentine central bank reach the lowest level since 2016. (Source: Bloomberg 20230626.)
- June 2023: For the first time ever, Argentina uses funds worth USD \$1bn drawn down from the PBOC swap line to repay IMF debts.
- August 2023: Argentina makes another payment worth USD \$1.7bn to the IMF, also drawn from the PBOC swap line.
- August 2023: Argentina devalues the peso against the USD by 18%.
- October/November 2023: Javier Milei is elected president of Argentina. Sergio Massa wins the first round of the presidential election. But Milei wins 55.7% of the popular vote in the second round, which is the highest winning margin since Argentina's transition to democracy.
- December 2023: Milei devalues the official peso exchange rate by more than 50% on taking office. (Source: Financial Times 20241009.)
- December 2023: The SIRA requirement is abolished and replaced with a simplified system (Sistema Estadístico de Importaciones, or SEDI). The BCRA started issuing a bond (Bonos para la Reconstrucción de una Argentina Libre, or BOPREAL) to help importers pay debts to international suppliers.
- April 2024: The Milei government achieves a first-quarter primary fiscal surplus, the first of its kind in 16 years. (Source: Reuters 20240517.)
- June 2024: The BCRA announces it has renewed a portion of its currency swap with China, worth around USD \$5bn, for another two years until July 2026. The funds are meant to be used to make payments owed to the IMF and to finance imports. Argentina is scheduled to begin paying down the active portion of the swap starting in mid-2025 over a 12-month period. (Source: Bloomberg 20240612.)

• October 2024: Milei says Argentina is not ready to lift its currency controls. The controls were imposed by a previous government in 2019 amid an economic crisis. They "fix the peso at an official rate and limit individual and company purchases of foreign currency, creating a black market for the US currency." (Source: Financial Times 20241009.)

Figure A.1: RMB invoicing for imports from China: Robustness

Notes: Panel A shows the share of import transactions from China invoiced in RMB for small and large importers. Importer size is measured as total imports from the world in 2022. These categories are defined such that half of the firms belong to each group. Panel B shows estimated time dummies from a regression using transaction-level data on imports from China in which the dependent variable is a dummy variable for transactions invoiced in RMB and including time dummies and firm × HS8 product fixed effects. This regression is estimated separately for small and large importers.

A) By importer size: Share of transactions in RMB B) By importer size: Probability of RMB invoicing

Notes: Panels A thorugh C show the number of transactions (in thousands) invoiced in RMB, US dollars, and other currencies. Panels D through F show the value of imports (in million US dollars) invoiced in RMB, US dollars, and other currencies.

Notes: This figure shows total imports from China and the rest of the world in millions of US dollars.

Figure A.4: RMB invoicing for imports from China: Differentiated vs. nondifferentiated products

Notes: This figure shows the share of import transactions from China invoiced in RMB for differentiated and nondifferentiated products following the Rauch (1999) classification.
