

# Democratizing Opportunity: The Effects of the U.S. High School Movement

NBER Summer Institute

Alison Doxey, Ezra Karger, and Peter Nencka

July 2025

# The High School Movement

- The fastest increase in schooling in American history
- Between 1890 and 1945, the number of public high schools in the United States increased from 2,771 to 23,757 (Goldin 1994, 1996, 1998)
- 15- to 18-year-olds' high school enrollment increased from 18% in 1910 to 73% in 1940
- High school graduation rate increased from 9% of 18-year-olds in 1910 to 50% in 1940
- Women graduated at higher rates than men until the 1940s (Goldin 2008, 2021)

**Claudia Goldin, *Career and Family* (2021)**

Youths flocked to the new high schools. But in the 1920s **girls attended and graduated at greater rates than boys did, in every state in the nation.**

Females had superior aptitude in high schools and higher graduation rates, just as they have greater college enrollment and graduation rates than do males today. Girls, it seems, do better at school when allowed to excel at it.

## Coincides with key trends

Between 1890 and 1940:

- the percentage of women aged 25 to 44 in the labor force grew from 15 to 35%, with even larger increases for white, married women (Goldin, 2006)

## Coincides with key trends

Between 1890 and 1940:

- the percentage of women aged 25 to 44 in the labor force grew from 15 to 35%, with even larger increases for white, married women (Goldin, 2006)
- the share of the U.S. population living in urban areas grew from 30 to 58% (Boustan et. al, 2013)

## Coincides with key trends

Between 1890 and 1940:

- the percentage of women aged 25 to 44 in the labor force grew from 15 to 35%, with even larger increases for white, married women (Goldin, 2006)
- the share of the U.S. population living in urban areas grew from 30 to 58% (Boustan et. al, 2013)
- the share of employed chemists increased by 600%; engineers by 700% (Goldin and Katz, 1999)

## Coincides with key trends

Between 1890 and 1940:

- the percentage of women aged 25 to 44 in the labor force grew from 15 to 35%, with even larger increases for white, married women (Goldin, 2006)
- the share of the U.S. population living in urban areas grew from 30 to 58% (Boustan et. al, 2013)
- the share of employed chemists increased by 600%; engineers by 700% (Goldin and Katz, 1999)
- the U.S share of world industrial output grew from 13 to 35%, surpassing the UK and Germany to be #1 in both aggregate and per-capita terms (Wright, 1990)

## Challenges

Despite widespread belief that the high school movement dramatically changed U.S society, it is difficult to study its causal impact on individuals:

# Challenges

Despite widespread belief that the high school movement dramatically changed U.S society, it is difficult to study its causal impact on individuals:

1. Need data on [local access to schools](#)

→ Important variation within states/counties

# Challenges

Despite widespread belief that the high school movement dramatically changed U.S. society, it is difficult to study its causal impact on individuals:

1. Need data on **local access to schools**

- Important variation within states/counties

2. Need consistent data on **long-run outcomes**

- Completed education not tracked until the 1940 census, and even then high school graduation information measured with error (Goldin, 1998)

- In the recent past it was nearly impossible to link large samples of women forward from childhood to their adult outcomes during this period

## This project

We construct a new panel of [all U.S. high schools](#) pre-1945 and when they were built

We then estimate the effect of local HS opening on:

1. Short-run enrollment
2. Medium-run labor market outcomes
3. Marriage, fertility, and geographic mobility

## **Preview of results**

We find striking heterogeneity in access to high schools, even within otherwise-similar, narrow geographic units

## Preview of results

We find striking heterogeneity in access to high schools, even within otherwise-similar, narrow geographic units

We estimate that high school construction:

1. **Increases** self-reported enrollment at high school ages (“first-stage”)
2. **Shifts** women into the workforce
3. **Shifts** men (and women) into more lucrative occupations
4. **Delays** marriage and induces geographic mobility

# Contributions

## **What happened during the US High School Movement?**

Reese (1995); Goldin (1998, 1999, 2021); Goldin and Katz (2008)

## **What are the effects of increased investment in local schools?**

Duflo (2001); Aaronson and Mazumder (2011); Schmick and Shertzer (2020); Jackson and Mackevicius (2023); Cascio and Lewis (2024)

## **What factors have influenced women's increased labor force participation?**

Greenwood et al. (2005); Bailey (2006); Albanesi and Olivetti (2016); Goldin (2021); Rashid (2025)

**Background**

**Data**

**Short-run enrollment impacts**

**Medium-run labor market impacts**

**Mechanisms**

**Robustness**

## What did high schools do?

### **Barbara McClintock (b. 1902), 1983 winner of Nobel Prize in Physiology/Medicine**

At Erasmus Hall High School, she discovered science. It was there that the pleasure of solving difficult problems began to grow. “I would solve some of the problems in ways that weren’t the answers the instructor expected....It was a tremendous joy, the whole process of finding that answer, just pure joy.” (Keller, 1983)

## What did high schools do?

### **Lucy Gambol (b. 1875), the first Black teacher in Omaha, Nebraska public schools**

“I am the oldest of eight children... I started to attend Omaha high school, and graduated from there in 1893. During this time there was a Normal Training school...and I attended it for two years finishing in 1895...which in turn afforded me the opportunity to teach in the public schools of Omaha...[My daughters] are both graduates of the University of Nebraska.” (American Life Histories, 1939)

# High school curriculum

- Pre-1890 a typical high school (especially on East Coast) was aimed at college preparation, mostly for men
  - Classics curriculum (e.g., Latin, Greek, Literature, Formal Math)

## High school curriculum

- Pre-1890 a typical high school (especially on East Coast) was aimed at college preparation, mostly for men
  - Classics curriculum (e.g., Latin, Greek, Literature, Formal Math)
- Shifts in late 1890s toward more practical classes, including applied science
- Some vocational training introduced (e.g., 17 percent of students report taking typing in 1934) but purely industrial training tracks failed (Goldin, 1998)

**Background**

**Data**

**Short-run enrollment impacts**

**Medium-run labor market impacts**

**Mechanisms**

**Robustness**

## High School Data

We construct the first complete panel of high schools in the U.S. pre-1945, based on:

1. Censuses of all public and private high schools, collected by the Bureau of Education every 1-2 years from 1873 to 1905; and in 1912 and 1951.
2. Lists of accredited high schools published by the Bureau of Education every 2-6 years from 1911 through 1944.
3. Patterson's American Educational Directories, providing names of high schools in each county for seven years between 1906 and 1924.
4. Private School Universe Surveys produced by the National Center for Education Statistics, including founding dates of high schools reported in the 1989 and 1995 academic years.

State and post-office.	Name.	Principal.	Classification of public high schools.	Secondary instructors.		Students.

# High School Data

Combine sources to create standardized panel

1. Scan PDFs manually or find scans already digitized by libraries
2. Digitize and fix errors by hand
3. Result: 360,000 year-by-high school observations in 26,877 unique geocoded places
4. Data ranges from only accreditation status in some years to detailed enrollment and financial statistics in other years

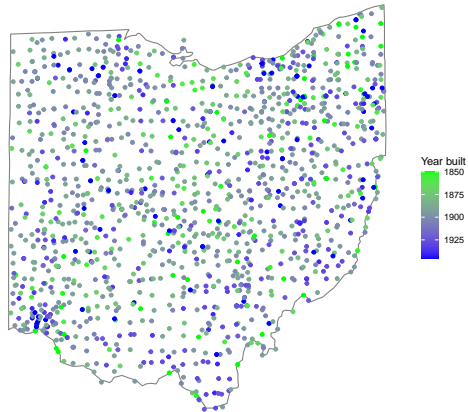

*Figure:* Map of cities by year of first high school constructed

*Notes:* This map shows the founding dates of the first high school built in each of 26,877 places that we map to a valid longitude-latitude.

*Figure:* Map of cities by year of first high school constructed, Ohio

*Figure:* Map of cities by year of first high school constructed, Massachusetts

*Figure:* Map of cities by year of first high school constructed, Tennessee

*Figure:* Number of towns in the U.S. with high schools, by year

*Notes:* This plot shows the number of towns and cities with any high school (the solid line) and with any public high school (the dashed line) from 1800 to 1950.

## Linking high schools to the census

Geocode all the high schools and match via lat-lon to individual data from the complete count decennial censuses for 1850 to 1940

Use the Census Place Project (Berkes, Karger, Nencka, 2023) to geocode small towns in the historical census

Link both men and [women](#) forward from their childhood homes to see age 20s and 30s outcomes using the Census Tree (Buckles, Haws, Price, Wilbert, 2023)

**Background**

**Data**

**Short-run enrollment impacts**

**Medium-run labor market impacts**

**Mechanisms**

**Robustness**

## Estimation intuition

*For students from the **same birth cohort**, whose nearest school opened in the **same year**, how do outcomes differ between those living with a high school in their town vs their peers living in a town a few miles away?*

- Assign youth to the closest high school that opened near them. If multiple schools within 1 mile, pick the one that opened earliest (treatment group). Further away, pick the closest one and record the opening date (control group)
- Trace out impacts for both treatment and control groups relative to age at high school opening after partialling out birth cohort by school opening year fixed effects
- Analogous to a “stacked” difference-in-difference – **event time is defined for all units**

# Enrollment effects

$$Y_{ictk} = \sum_{a=-30}^{60} \beta_a (Treated_i \times \mathbf{1}[\text{age} = a]_{ictk}) + \lambda_b + \delta_c + \gamma_{st} + \eta_t + \phi_{kb} + \epsilon_{ictk}$$

- $Y_{ictk}$ : Enrollment for person  $i$ , living in childhood city  $c$ , in year  $t$  whose nearby high school opened in year  $k$ .
- $Treated_i$ : An indicator equal to 1 if  $c$  is  $\leq 1$  mile from a high school.
- $\mathbf{1}[\text{age} = a]_{ictk}$ : An indicator for person  $i$  being age  $a$  when a school opened in year  $k$ .
- $\lambda_b$ ,  $\delta_c$ ,  $\eta_t$ , and  $\gamma_{st}$ : birth year, city, year, and state-by-year FEs
- $\phi_{kb}$ : **School Opening Year**  $\times$  **Birth Cohort FE**. Controls for trends common to a birth cohort exposed to a school that opened in a specific year.

# Enrollment effects

$$Y_{ictk} = \sum_{a=-30}^{60} \beta_a (Treated_i \times \mathbf{1}[\text{age} = a]_{ictk}) + \lambda_b + \delta_c + \gamma_{st} + \eta_t + \phi_{kb} + \epsilon_{ictk}$$

- Plot  $\beta_a$ , which track the average effect of **proximate access** ( $\leq 1$  miles) to a high school by age at HS opening.

# Enrollment effects

$$Y_{ictk} = \sum_{a=-30}^{60} \beta_a (Treated_i \times \mathbf{1}[\text{age} = a]_{ictk}) + \lambda_b + \delta_c + \gamma_{st} + \eta_t + \phi_{kb} + \epsilon_{ictk}$$

- Plot  $\beta_a$ , which track the average effect of **proximate access** ( $\leq 1$  miles) to a high school by age at HS opening.
- **Intuition:** If a high school opened in your childhood town when you were 12, you had access. If you were 28 – no access. Benchmark differences in outcomes across those ages to the same age comparisons for people in a city  $> 2$  miles from the school

## Enrollment effects

$$Y_{ictk} = \sum_{a=-30}^{60} \beta_a (Treated_i \times \mathbf{1}[\text{age} = a]_{ictk}) + \lambda_b + \delta_c + \gamma_{st} + \eta_t + \phi_{kb} + \epsilon_{ictk}$$

- Plot  $\beta_a$ , which track the average effect of **proximate access** ( $\leq 1$  miles) to a high school by age at HS opening.
- **Intuition:** If a high school opened in your childhood town when you were 12, you had access. If you were 28 – no access. Benchmark differences in outcomes across those ages to the same age comparisons for people in a city  $> 2$  miles from the school
- **Pretrends:** Does it matter if your high school opened 10 years too late for you to attend or only 5 years too late?

# Enrollment effects

$$Y_{ictk} = \sum_{a=-30}^{60} \beta_a (Treated_i \times \mathbf{1}[\text{age} = a]_{ictk}) + \lambda_b + \delta_c + \gamma_{st} + \eta_t + \phi_{kb} + \epsilon_{ictk}$$

- Plot  $\beta_a$ , which track the average effect of **proximate access** ( $\leq 1$  miles) to a high school by age at HS opening.
- **Intuition:** If a high school opened in your childhood town when you were 12, you had access. If you were 28 – no access. Benchmark differences in outcomes across those ages to the same age comparisons for people in a city  $> 2$  miles from the school
- **Pretrends:** Does it matter if your high school opened 10 years too late for you to attend or only 5 years too late?
- Cluster standard errors at the high school level

**Medium-run labor market impacts**

**Mechanisms**

**Robustness**

## Medium-run effects

Measure labor market and demographic outcomes at age 26-28 and 36-38 by linking forward from childhood outcomes using the Census Tree (Buckles, Haws, Price, Wilbert, 2023)

Estimate identical event-study regressions as we did for enrollment

Results are at the [individual level](#), not the place level. We assign treatment based on childhood home and birth-year but measure outcomes wherever we see people at later ages

# Identification

Were cities that established high schools trending differently?

- Test directly using pre-trends
- No pre-trends in enrollment data

# Identification

Were cities that established high schools trending differently?

- Test directly using pre-trends
- No pre-trends in enrollment data

Were there other time-varying differences between treated and control cities?

- Other institutions starting at similar times?
- Differential migration?

**Data**

**Short-run enrollment impacts**

**Medium-run labor market impacts**

**Mechanisms**

**Robustness**

*Figure:* Baseline female LFP result (2+ mile control group)

*Figure:* Baseline female LFP result (4+ mile control group)

*Figure:* Baseline female LFP result (6+ mile control group)

## Other robustness

Results robust to

1. Controlling for county-by-year fixed effects
2. Excluding birthyr-by-state and birthyr-by-treatment cohort FEs
3. Conditioning on interacted town-level 1860 characteristic by birthyr controls (for the subsample of post-1860 HS locations)
4. Limiting the sample to youth who were in the same location in their high school years and early childhood (to exclude the potential of endogenous movers)
5. Expanding the age ranges

# Conclusion

- Tremendous variation in access to high schools, even within counties
- High schools increase local school attendance, but only for high-school aged students
- High school access leads to occupational upgrading for men
- High school access shifts women into the workforce, into higher-paying occupations, and delays marriage
